Fréchet Isotopies to Monotone Curves*

Kevin Buchin† Erin Chambers‡ Tim Ophelders§ Bettina Speckmann†

1 Introduction

We study the isotopic Fréchet distance, which is a distance measure between two curves \( f \) and \( g \) that captures one notion of an optimal morph between these two curves. The classic Fréchet distance between \( f \) and \( g \), also called the “dog leash distance”, measures the length of the shortest possible straight leash needed to connect a man and a dog which are walking forward along \( f \) and \( g \). Any two feasible walks using such a straight leash induce a Fréchet matching between \( f \) and \( g \). One can now imagine to build a morph between \( f \) and \( g \) by sliding each point of \( f \) along the leash that connects it to its matched point on \( g \). Such an approach will work well in unrestricted Euclidean space, however, it is not suitable for more general spaces that might contain obstacles. In the presence of obstacles the leashes of the classic Fréchet distance can jump discontinuously and hence the resulting morph would be discontinuous as well.

The homotopic Fréchet distance \([3, 6]\) forces leashes to move continuously. More formally, for two curves \( f \) and \( g \): \([0, 1] \rightarrow \mathbb{R}^2\) in the plane a homotopy \( h: [0, 1]^2 \rightarrow \mathbb{R}^2\) is a continuous map between \( f \) and \( g \). Such a homotopy essentially morphs one curve into the other: each point of \( f \) traces a path \( h(p, \cdot) \) to a point on \( g \). The length of a homotopy is the length of the longest such path, and a Fréchet homotopy is one that minimizes this length. The homotopic Fréchet distance between \( f \) and \( g \) is then the length of a Fréchet homotopy between \( f \) and \( g \). The homotopic Fréchet distance and the classic Fréchet distance are equivalent in \( \mathbb{R}^2 \). The morph that results from a Fréchet homotopy is continuous, but it may change the structure of the input curves during the morph: intermediate curves can self-intersect or collapse to a point, even if \( f \) and \( g \) are simple curves.

A homotopy is an isotopy if all its intermediate curves \( h(\cdot, t) \) are simple. The isotopic Fréchet distance measures the length of an optimal isotopy between \( f \) and \( g \); we call an optimal isotopy a Fréchet isotopy. The study of Fréchet isotopies was initiated in \([4]\). The authors gave some simple observations and examples and showed that the isotropic Fréchet distance in the plane can be arbitrarily larger than the homotopic Fréchet distance.

Results. In this paper we revisit the isotopic Fréchet distance and refute a conjecture posed in \([4]\). We also give the first algorithms to compute short isotopies in some restricted cases. Specifically, we compute optimal isotopies if there is a direction in which both input curves are monotone. Furthermore, given a curve in \( \mathbb{R} \times [0, \varepsilon] \) (for infinitesimally small \( \varepsilon \)), we construct an isotopy to a monotone curve using minimal length.

Related work. Closely related are morphs based on geodesic width \([5]\): the intermediate curves are not allowed to cross the input curves \( f \) and \( g \) and they are restricted to the area between the leashes connecting the endpoints of \( f \) and \( g \). This restriction naturally enforces intermediate curves without self-intersections since “geodesic leashes” do not cross each other. Morphs based on geodesic width minimize the maximum leash length. However, they are restricted to input curves that do not intersect each other; in contrast, Fréchet isotopies are also well-defined for input curves that intersect each other.

A variety of morphs have been considered in the graph drawing and computational geometry literature. For instance, it is well known that any two drawings of the same planar graphs can be morphed into one another. More recent work focused on bounding the number of steps in the optimal morph between any two input graphs \([1, 2]\). Here the intermediate curves are homeomorphic to the input and vary continuously. However, in contrast to Fréchet isotopies, the morphs do not minimize length.

2 Preliminaries

A curve in the plane is a continuous map \( f: [0, 1] \rightarrow \mathbb{R}^2 \). We denote the \( x \) and \( y \)-coordinates of \( f(p) \) by \( f_x(p) \) and \( f_y(p) \), respectively. A continuous nondecreasing surjection \( \alpha: [0, 1] \rightarrow [0, 1] \) is called a reparameterization of a curve. A homotopy is a continuous map \( h: [0, 1] \times [0, 1] \rightarrow \mathbb{R}^2 \). We denote its level curves by \( h_t: p \mapsto h(p, t) \), and say \( h \) goes from curve \( f \) to \( g \) if \( h_0 = f \) and \( h_1 = g \). A homotopy is an isotopy if each curve \( h_t \) is simple.
A homotopy from \( f \) to \( g \) traces paths \( \lambda_{h,p} : t \mapsto h(p,t) \) between the points \( f(p) \) and \( g(p) \), and such a path is traditionally referred to as a leash. Let the length of a homotopy \( h \) be the length \( \text{length}(h) = \sup_p \text{length}(\lambda_{h,p}) \) of its longest leash. We are interested in homotopies \( h \) minimizing this length and define the homotopic Fréchet distance between \( f \) and \( g \) as

\[
d_{\text{hom}}(f, g) = \inf_{h \in \text{hom}(f, g)} \text{length}(h),
\]

where \( h \) ranges over homotopies and \( \alpha \) and \( \beta \) range over reparameterizations. The isotopic Fréchet distance \( d_{\text{iso}} \) is defined similarly, except that \( h \) ranges over isotopies.

The Fréchet distance \( d_F(f, g) = \inf_{\alpha, \beta} \sup_p \| f \circ \alpha(p) - g \circ \beta(p) \| \) is a related measure that does not require leashes to trace out a homotopy, so each leash can be assumed to be a shortest path. The pair \((\alpha, \beta)\) is called a matching. We define the cost of a matching \((\alpha, \beta)\) between \( f \) and \( g \) as \( \text{cost}_{f,g}(\alpha, \beta) = \sup_p \| f \circ \alpha(p) - g \circ \beta(p) \| \). A Fréchet matching between curves \( f \) and \( g \) in the plane is one with cost \( d_F(f, g) \).

In the plane, the map \( \text{Aff}^{f,g}(p, t) = (1 - t) \cdot f(p) + t \cdot g(p) \) using line segments (shortest paths) as leashes is a homotopy since it is an affine interpolation between continuous maps. We call \( \text{Aff}^{f,g} \) the affine homotopy from \( f \) to \( g \), and its length is \( \text{length}(\text{Aff}^{f,g}) = \sup_p \| f(p) - g(p) \| \). It follows that the homotopic Fréchet distance and the Fréchet distance are equivalent in \( \mathbb{R}^2 \). On the other hand, the isotropic Fréchet distance in the plane can be arbitrarily larger than the homotopic Fréchet distance [4].

We call a homotopy \( h \) from \( f \circ \alpha \) to \( g \circ \beta \) a Fréchet homotopy if \( \text{length}(h) = d_{\text{hom}}(f, g) \), and call \( h \) a Fréchet isotopy if \( h \) is an isotopy with \( \text{length}(h) = d_{\text{iso}}(f, g) \). Since every isotopy is a homotopy, we have \( d_{\text{hom}}(f, g) \leq d_{\text{iso}}(f, g) \) and any isotopy that is a Fréchet homotopy is also a Fréchet isotopy. However, Fréchet isotopies need not be Fréchet homotopies since there might exist a homotopy shorter than any isotopy.

For a curve \( f \) and a unit vector \((x, y) \in S^1\), we define the directional length of \( f \) in the direction \((x, y) \) to be the total length that \( f \) moves forward in the direction of the vector, given by \( \text{length}_{(x,y)}(f) = \int_0^1 \max(0, \langle d_f(p), (x,y) \rangle) \text{d}p \), where \( \langle \cdot, \cdot \rangle \) is the inner product. We define the horizontal length of a curve as \( \text{length}_{\text{hor}}(f) = \text{length}_{(-1,0)}(f) + \text{length}_{(1,0)}(f) \) and define the horizontal homotopic and isotopic Fréchet distances using the horizontal length function. As usual, a horizontal Fréchet homotopy (respectively isotopy) is one minimizing the horizontal homotopic (respectively isotopic) Fréchet distance.

Throughout the paper, we assume all input curves to be simple.

3 Disproving a conjecture

In Figure 1 we show an example of two zig-zag curves, originally presented in [4]. The Fréchet distance between these curves is at most \( \varepsilon \), as there is a matching whose leashes are all vertical. However, this Fréchet mapping yields a homotopy that collapses the zig-zag to a flat line before re-expanding to the other zig-zag, which does not result in an isotopy, as the three segments coincide halfway along the isotopy.

In [4], the authors conjectured that the isotopic Fréchet distance between the zig-zags is \( \sqrt{L^2 + \varepsilon^2} \). However, the isotopy demonstrated by the green leashes on the right side of Figure 1 has length arbitrarily close to \( \sqrt{L^2 + \varepsilon^2}/2 + \varepsilon/2 \).

We will show that the isotopy of Figure 1 is arbitrarily close to optimal. Consider a convex region \( D \) and an isotopy \( h \) between curves \( f \) and \( g \) in the plane, where the endpoints of all intermediate curves lie in \( D \); that is, \( \text{Im}(\lambda_{h,0}) \subseteq D \) and \( \text{Im}(\lambda_{h,1}) \subseteq D \). Fix some \( p \in (0,1) \) and denote by \( \text{poly}_t \) the polyline with an edge from \( h(0,t) \) to \( h(p,t) \), and an edge from \( h(p,t) \) to \( h(1,t) \). Let \( \theta_t \) be the (counterclockwise) angle at \( h_t(p) \) between the two edges of \( \text{poly}_t \) (plus a multiple of 360 degrees), such that \( \theta_t \) varies continuously with \( t \). We show in Lemma 1 that (in any isotopy from \( \text{poly}_0 \) to \( \text{poly}_1 \)) the leash \( \lambda_{h,p} \) must intersect \( D \) if \( \theta_0 \) and \( \theta_1 \) differ by at least 180 degrees, see Figure 2.

Figure 2: Curves \( f = h_0, g = h_1 \) and polylines \( \text{poly}_0 \) and \( \text{poly}_1 \) with endpoints in convex region \( D \).
Lemma 1 If $f$ is isotopic to $\text{poly}_0$ relative to its vertices and $g$ is isotopic to $\text{poly}_1$ relative to its vertices, and $|\theta_l - \theta_0| \geq 360$, then $h(p,t) \in D$ for some $t$.

Proof. Because $f$ and $g$ are isotopic to $\text{poly}_0$ and $\text{poly}_1$ respectively (relative to their vertices), we may assume without loss of generality that $0 \leq \theta_0 < 360$ and $0 \leq \theta_1 < 360$. Because $\theta_l$ varies continuously, we have by the intermediate value theorem that $\theta_l = 180$ for some $t \in [0,1]$. Hence, $h(p,t)$ lies on the line segment between $h(0, t) \in D$ and $h(1, t) \in D$. By convexity, this segment lies completely in $D$, so $h(p,t) \in D$. \quad \square

Figure 3: The vertices and region $D$ used to obtain a lower bound for the curves of Figure 1.

Using Lemma 1, we can show that our isotopy for the zig-zags of Figure 1 is optimal as $\varepsilon$ approaches 0. For this, we show that any Fréchet isotopy has length at least $L/2$. Assume that the zig-zags $f$ and $g$ are parameterized such that an isotopy $h$ of length less than $L/2$ between them exists. Let $l$ be the vertical line centered between the vertices, such that each vertex has distance $L/2$ to $l$, and let $D$ be the half-plane to the left of $l$, see Figure 3. Let $f(a), f(b)$ and $f(c)$ be the first three vertices of $f$. If $\text{length}(h) < L/2$, the leashes $\lambda_h, a$ and $\lambda_h, c$ lie completely inside $D$, and $\lambda_h, b$ lies completely outside $D$. Since $a < b < c$ and $g(b) \notin D$, $a$ and $c$ lie in different components of $g^{-1}(D)$. Isotopy $h$ induces a restricted isotopy between the subcurves of $f$ and $g$ from $a$ to $c$, and these subcurves satisfy the conditions required by Lemma 1. Therefore, $\text{Im}(\lambda_{h,b})$ intersects $D$, so $\text{length}(h) \geq L/2$.

4 Isotopies between monotone curves

A curve $f$ is strictly $x$-monotone if $f_x(p) < f_x(p')$ for all $p < p'$. Lemma 2 implies that for such curves, the isotopic and homotopic Fréchet distances are equal.

Lemma 2 For strictly $x$-monotone curves $f$ and $g$, each curve $h_t$ of $h = \text{Aff}^f g$ is strictly $x$-monotone.

Proof. Recall that $h_t(p) = (1 - t) \cdot f(p) + t \cdot g(p)$. Consider the $x$-coordinates $x_t(p)$ of $h_t(p)$ and $x_t'(p')$ of $h_t(p')$ for $p < p'$. Let $s_t = x_t(p') - x_t(p)$. Because $f$ and $g$ are strictly $x$-monotone, we have $x_0(p) < x_0(p')$ and $x_1(p) < x_1(p')$, so $s_0 > 0$ and $s_1 > 0$. Since $s$ is affine, we have $s(t) > 0$ for $t \in [0,1]$, so $x_t(p) < x_t(p')$. Hence, each level curve $h_t$ is strictly $x$-monotone. \quad \square

Theorem 3 For strictly $x$-monotone curves, the homotopic and isotopic Fréchet distances are equivalent.

5 Isotopies to monotone curves

In this section, we consider the problem of monotonizing curves using minimal horizontal movement. Specifically, we show how to construct a short isotopy from an input curve to some $x$-monotone curve. In Section 5.1 we argue that this problem is interesting already if we measure only horizontal length by showing that an optimal isotopy may have non-monotone leashes, even though we can choose any $x$-monotone target curve. We construct an isotopy of minimal horizontal length to an $x$-monotone curve in Section 5.2. We first give a lower bound for homotopies to $x$-monotone curves.

Lemma 4 For any homotopy $h$ from $f$ to any $x$-monotone curve $g$, $\text{length}_{\text{hor}}(h) \geq \frac{1}{2} \sup_{p \leq p'} f_x(p) - f_x(p')$.

Proof. We have $\text{length}_{\text{hor}}(\lambda_{h,p}) \geq |f_x(p) - g_x(p)|$ and because $g$ is $x$-monotone, $g_x(p) \leq g_x(p')$. Because $\text{length}_{\text{hor}}(h) \geq \text{length}_{\text{hor}}(\lambda_{h,p}) \geq f_x(p) - g_x(p)$ and $\text{length}_{\text{hor}}(h) \geq \text{length}_{\text{hor}}(\lambda_{h,p'}) \geq g_x(p') - f_x(p')$, we have $2 \cdot \text{length}_{\text{hor}}(h) \geq f_x(p) - g_x(p) + g_x(p') - f_x(p') \geq f_x(p) - f_x(p')$. \quad \square

5.1 Non-monotone isotopies

Consider the curve $f = h_0$ of Figure 4 with $f(0) = p_0$ and $f(1) = p_5$, morphing into an $x$-monotone curve $g = h_1$ as depicted. No matter how small we pick $\varepsilon > 0$, the depicted isotopy has length at most $r + \varepsilon$ if $w < r$. By Lemma 4, there exists no homotopy to an $x$-monotone curve of length less than $r$, even if we pick a different $x$-monotone curve $g$. In this context, the lemma states that because $f_x(p_1) \geq f_x(p_2) + 2r$ and $g_x(p_1) \leq g_x(p_2)$, one of the leashes $\lambda_{h,p_1}$ or $\lambda_{h,p_2}$ has length at least $r$ in any homotopy $h$.

Figure 4: A curve for which any Fréchet isotopy to an $x$-monotone curve moves some point for distance $w/2 - \varepsilon$ in both the positive and the negative $x$-direction.
What makes this instance interesting is that any optimal isotopy moves some points in both the forward (positive) and backward (negative $x$-direction) for a considerable distance. Formally, for any isotopy $h$ from $f$ to $g$, we have both $\text{length}_{(1,0)}(h_{t,p}) \geq w/2 - \varepsilon$ and $\text{length}_{(-1,0)}(h_{t,p}) \geq w/2 - \varepsilon$ for some $p$. In particular, consider the two endpoints $f(p_0)$ and $f(p_5)$ in Figure 4. Based on Lemma 1, these points must ‘untangle’ with respect to each other somewhere in the isotopy $h$. For this, the $x$-coordinates of $h_t(p_0)$ and $h_t(p_5)$ must be equal for some value of $t$, say for $t = t^*$. Because $g$ is $x$-monotone, and an optimal isotopy has length at most $r + \varepsilon$, we have $g_x(p_0) \leq g_x(p_2) \leq f_x(p_2) + r + \varepsilon = f_x(p_0) + \varepsilon$ and symmetrically $f_x(p_5) - r - \varepsilon \leq g_x(p_5) \leq g_x(p_0)$.

Let $\gamma = h_t^*$ and $x^* = \gamma_x(p_0) = \gamma_x(p_5)$. Since $f_x(p_5) - f_x(p_0) = w$, we have $x^* - f_x(p_0) \geq w/2$ or $f_x(p_5) - x^* \geq w/2$. If $x^* - f_x(p_0) \geq w/2$, we also have $g_x(p_0) - x^* \geq w/2 - \varepsilon$, so $p_0$ moves forward for a distance of at least $w/2$ and backwards for a distance of at least $w/2 - \varepsilon$. Otherwise, $f_x(p_5) - x^* \geq w/2$, and $p_5$ moves backwards for $w/2$ and forwards for $w/2 - \varepsilon$. The total distance such points move approaches $d_{iso}(f, g)$ as $\varepsilon$ approaches 0.

5.3 Optimality of the isotopy to a monotone curve

Lemma 4 gave us a lower bound on $\text{length}_{opt}(h)$ for a homotopy $h$ turning $f$ into an $x$-monotone curve. Theorem 5 (proof in the full paper) tells us that the horizontal length of the isotopy we construct matches this lower bound, meaning that the isotopy yields an $x$-monotone curve using minimal horizontal movement.

Theorem 5 $\text{Shr}^I(t)$ yields an $x$-monotone curve at $t = |\text{Im}(f_x)|^{-1} \frac{1}{2} \sup_{p \leq p'} f_x(p) - f_x(p')$, using only $\frac{1}{2} \sup_{p \leq p'} f_x(p) - f_x(p')$ horizontal movement.
