A Typechecker for Bijective Pure Type Systems

Erik Poll

Abstract. A type inference algorithm is given, which closely follows to the type derivation rules for Pure Type Systems. Soundness and completeness of the algorithm are proved for a large class of Pure Type Systems, which includes all systems in Barendregt's λ-cube.

* supported by the Dutch organization for scientific research (NWO).
1 Introduction

For a Pure Type System (PTS) (see [Bar92]) the central notion is that of type assignment. Every PTS comes with its typing relation $\vdash$, defined by a set of inference rules. Type judgements are of the form $\Gamma \vdash a : A$ – in context $\Gamma$ the term $a$ has type $A$ – where $\Gamma$ is a list of type assignments to variables.

For an implementation of a PTS a reasonably efficient type-checker is needed. (If a type-checker reduces types to their normal forms we do not consider it to be 'reasonably efficient'.) It is not difficult to define a type-checker that closely follows the type inference rules (see [Pol92]). Proving soundness of this algorithm is easy, but all attempts at proving completeness have so far failed.

Instead of type judgements of the form

$$x_1 : A_1, \ldots, x_n : A_n \vdash a : A$$

we consider more informative judgements of the form

$$x_1 : A_1 : s_1, \ldots, x_n : A_n : s_n \vdash a : A : s$$

These judgements do not only involve the types of terms but also the types of these types. In this new typing relation a term has exactly the same types as in the old typing relation.

As for the original typing relation, for the new typing relation $\vdash$ there is a natural type-checking algorithm which closely follows the type inference rules. For this type-checking algorithm soundness and completeness can be proved by straightforward induction proofs for a large class of PTS, which we call the bijective PTS (definition 3.5 on page 9). The bijective PTS are a subclass of the functional PTS. It includes all functional PTS with rules of the form $(s_1, s_2, s_2)$, and hence all systems in Barendregt's $\lambda$-cube.

In the next section we recall the definition of a PTS given in [Bar92] and discuss the problem of type-checking PTS.

Then, in section 3, a new typing relation is introduced, with judgements of the form

$$x_1 : A_1 : s_1, \ldots, x_n : A_n : s_n \vdash n : A : s.$$ Two versions of this typing relation are given: one that can be used for all functional PTS ($\vdash_f$) and one that can only be used for the bijective PTS ($\vdash_b$).

In section 4 a syntax-directed version $\vdash_{bsd}$ of the typing relation $\vdash_b$ is defined (definition 4.1). This typing relation gives a sound and complete type-checking algorithm for all strongly normalising bijective PTS.

In section 5 a syntax-directed version of the typing relation $\vdash_f$ for functional PTS is defined, for which proving completeness is a problem unfortunately.

Finally, in the last section, the main steps leading from the original typing relation to the syntax-directed one are outlined, and we sketch how the typechecker can be extended to include other primitives, such as $\Sigma$, $\times$, or $\pi$-types.

All the proofs that the different typing relations are equivalent are by induction on derivations and are given in the appendices.
2 Pure Type Systems

Definition 2.1. [Pure Type System]
A Pure Type System (PTS) is a triple \((S, A, R)\) with

- \(S\) is a set of symbols called the sorts
- \(A \subseteq S \times S\), a set of axioms.
- \(R \subseteq S \times S \times S\), a set of rules

Definition 2.2. [terms and contexts]
Given a PTS \((S, A, R)\), the collection of terms \(M\) and contexts \(\Gamma\) is given by

\[
M ::= x \mid s \mid (MM) \mid (\lambda x : M. M) \mid (\Pi x : M. M)
\]
\[
\Gamma ::= \epsilon \mid \Gamma, x : M
\]

where \(x\) is a variable and \(s\) is a sort.

Convention \(s, s_1, s'\), etc. range over \(S\); \(a, b, A, B, a',\) etc. range over terms.

Definition 2.3. [typing relation \(\Gamma \vdash b : B\)]
For each PTS \((S, A, R)\), a typing relation \(\vdash\) is defined. For type judgements of the form \(\Gamma \vdash b : B\) we have the following inference rules

\[
\begin{align*}
(axiom) & \quad \epsilon \vdash s : s' & \text{if } (s : s') \in A \\
(variable) & \quad \frac{\Gamma \vdash A : s}{\Gamma, x : A \vdash x : A} & x \text{ fresh} \\
(weakening) & \quad \frac{\Gamma \vdash b : B \quad \Gamma \vdash A : s}{\Gamma, x : A \vdash b : B} & x \text{ fresh} \\
(formation) & \quad \frac{\Gamma \vdash A : s_1 \quad \Gamma, x : A \vdash B : s_2}{\Gamma \vdash (\Pi x : A. B) : s_3} & \text{if } (s_1, s_2, s_3) \in R \\
(abstraction) & \quad \frac{\Gamma, x : A \vdash b : B \quad \Gamma \vdash (\Pi x : A. B) : s}{\Gamma \vdash (\lambda x : A. b) : (\Pi x : A. B)} \\
(application) & \quad \frac{\Gamma \vdash b : (\Pi x : A. B) \quad \Gamma \vdash a : A}{\Gamma \vdash ba : B[x := a]} \\
(conversion) & \quad \frac{\Gamma \vdash b : B \quad \Gamma \vdash B' : s \quad B \simeq B'}{\Gamma \vdash b : B'}
\end{align*}
\]

where \(s\) ranges over sorts, i.e. \(s \in S\), and \(\simeq\) is \(\beta\)-equality.

The most important subclass of PTS is that of the functional PTS. Most - if not all - PTS that are of practical interest are functional PTS.

Definition 2.4. A PTS \((S, A, R)\) is called functional (or singly sorted) iff

\[
(s : s') \in A \land (s : s'') \in A \quad \Rightarrow \quad s' \equiv s''
\]
\[
(s_1, s_2, s_3) \in R \land (s_1, s_2, s'_3) \in R \quad \Rightarrow \quad s_3 \equiv s'_3
\]

The distinguishing property of these PTS is that the type of a term is unique up to \(\beta\)-equality:

Lemma. [unicity of types for \(\vdash : UT_e\)]
For functional PTS: if \(\Gamma \vdash b : B\) and \(\Gamma \vdash b : B'\), then \(B \simeq B'\).
2.1 Typechecking Pure Type Systems

Two typechecking problems can be distinguished

- \( \Gamma \vdash b : B? \) - the type checking problem -
  given a context \( \Gamma \) and terms \( b \) and \( B \) decide whether \( \Gamma \vdash b : B \) derivable or not.

- \( \Gamma \vdash b : ? \) - the type inference problem -
  given a context \( \Gamma \) and a term \( b \), find a term \( B \) such that \( \Gamma \vdash b : B \), or report failure if no such \( B \) exists.

For functional PTS finding a single type for \( b \) suffices, as it is unique modulo \( \beta \). For non-functional PTS there may be several \( \beta \)-equivalence classes of types for \( b \), in which case we would want to find a representative of each one.

The second is the more general of the two problems: if we can solve \( \Gamma \vdash b : ? \) we can also solve \( \Gamma \vdash b : B? \). On the other hand, it is difficult to imagine a solution for \( \Gamma \vdash b : B? \) which does not also provide a way to solve \( \Gamma \vdash b : ? \).

The remainder of this section concerns our motivation for considering a new typing relation. We discuss the natural type inference algorithm for functional PTS defined in [PoI92], and the problem encountered for this algorithm, which is that nobody has been able to prove completeness. For the new typing relation introduced in the next section, we will not have this problem.

The obvious way to solve \( \Gamma \vdash b : ? \) is to try to construct a type derivation for \( b \) guided by the shape of \( b \). Here we run into the problem that that the PTS inference rules are very non-deterministic: there can be many derivations for \( \Gamma \vdash b : B \), let alone for \( \Gamma \vdash b : ? \). The source of this non-determinism is the conversion rule, which can be used at any point in a derivation. (The weakening rule also introduces non-determinism, but this can easily be eliminated by restricting the weakening rule to variables and sorts, as in the \( \Gamma \vdash \) weakening rule below).

Despite this non-determinism, it is not difficult to define a natural type inference algorithm which tries to construct a particular type derivation, by only doing conversions

- to test if a type reduces to a sort
- to test if the types of a function and its argument match

But then we are implementing the following syntax-directed system \( \Gamma_{sd} \) (\( sd \) for syntax-directed) : instead of \( \vdash \)

\[
\begin{align*}
\text{(axiom)} & \quad \epsilon \vdash_{sd} s : s' \quad \text{if } (s : s') \in A \\
\text{(variable)} & \quad \frac{\Gamma \vdash_{sd} A : S \quad S \rightarrow_{\beta} s}{\Gamma, x : A \vdash_{sd} x : A} \quad x \text{ fresh} \\
\text{(weakening)} & \quad \frac{\Gamma \vdash_{sd} b : B \quad \Gamma \vdash_{sd} A : S \quad S \rightarrow_{\beta} s}{\Gamma, x : A \vdash_{sd} b : B} \quad x \text{ fresh and } b \text{ a variable or sort} \\
\text{(formation)} & \quad \frac{\Gamma \vdash_{sd} A : S_1 \quad S_1 \rightarrow_{\beta} s_1}{\Gamma \vdash_{sd} (\Pi x : A. B) : S_2 \quad S_2 \rightarrow_{\beta} s_2} \quad \text{if } (s_1, s_2, s_3) \in R \\
\text{(abstraction)} & \quad \frac{\Gamma \vdash_{sd} A : A \vdash_{sd} b : B}{\Gamma \vdash_{sd} (\lambda x : A. b) : (\Pi x : A. B)} \\
\text{(application)} & \quad \frac{\Gamma \vdash_{sd} a : A \quad A \simeq A'}{\Gamma \vdash_{sd} ba : B \quad B[x := a]} \\
\end{align*}
\]

Here \( \rightarrow_{\beta} \) denotes \( \beta \)-reduction and \( \rightarrow_{wh} \) denotes weak-head reduction. Note that the weakening rule is restricted to variables and sorts. This means that in derivations weakening is postponed as much as possible. The shape of a term \( b \) determines a unique \( \Gamma_{sd} \)-type derivation for \( b \).
If our algorithm implements $\vdash_{sd}$ instead of $\vdash$, we want to know if $\vdash_{sd}$ and $\vdash$ are equivalent. This means we have to prove

\begin{align*}
\text{soundness: } & \Gamma \vdash_{sd} c : C \implies \Gamma \vdash c : C \\
\text{completeness: } & \Gamma \vdash c : C \implies (\exists C' \simeq C. \Gamma \vdash_{sd} c : C')
\end{align*}

It is easy to prove soundness. However, proving completeness is a problem. This means it is not known if for a functional PTS the algorithm can always find a type for a typeable term. (For non-functional PTS completeness fails; see [Po92] for a counterexample.)

A proof of completeness by induction on the derivation $\Gamma \vdash c : C$ fails in the abstraction rule:

Suppose the last step in the derivation of $\Gamma \vdash c : C$ is the abstraction rule. Then

$c \equiv (\lambda x : A. b), \ C \equiv (\Pi x : A. B)$ and the last step in the derivation is

\[
\Gamma, x : A, t : B, I \vdash (\Pi x : A. B) : s
\]

\[
\Gamma \vdash (\lambda x : A. b) : (\Pi x : A. B)
\]

By the induction hypothesis $\Gamma, x : A, t : B' \text{ for some } B' \simeq B$ and $\Gamma \vdash_{sd} (\Pi x : A. B) : S$ for some $S \simeq s$. However, the type $B'$ found for $b$ can be different from $B$ (but $\beta$-equivalent to $B$), and we do not know if $\Gamma \vdash_{sd} (\Pi x : A. B') : S'$ for some $S'$.

Basically, the problem is the way in which the subformula property fails for the abstraction rule: a type derivation for $(\lambda x : A. b)$ in context $\Gamma$ contains a sub-derivation of a term $(\Pi x : A. B)$ which is not a subterm of $(\lambda x : A. b)$.

An alternative abstraction rule, which is equivalent with the original abstraction rule, is

\[
\Gamma \vdash A : s_1 \quad \Gamma, x : A, t : B, \Gamma, x : A, t : B : s_2 \quad \Gamma \vdash (\lambda x : A. b) : (\Pi x : A. B)\] if $(s_1, s_2, s_3) \in R$

For this abstraction rule we have the same problem, this time caused by the premiss $\Gamma, x : A, t : B : s_2$ instead of the premiss $\Gamma, x : A, t : B : s_3$.

In section 6 two type checking algorithms are mentioned which successfully avoid this problem by relaxing the condition $\Gamma \vdash (\Pi x : A. B) : s$, or rather the condition $\Gamma, x : A, t : B : s_2$ in the alternative abstraction rule given above.

We avoid the problem by considering derivations for judgements of the form $\Gamma \vdash a : A : s$, as explained in the next section.
3 Type-kind derivations

Instead of judgements of the form

$$x_1 : A_1, \ldots, x_n : A_n \vdash a : A$$

we consider judgements of the form

$$x_1 : s_1, \ldots, x_n : s_n \vdash a : A : s$$

These judgements not only give the type of a term, but also the type of its type, which we call its kind. For example, in the judgement above $s$ is the kind of $a$ and each $s_i$ is the kind of $x_i$.

The notion of kind is related to the notion of degree - defined in [dB80] for the AUTOMATH languages and in [Bar92] for the $\lambda$-cube - in that terms with the same kind have the same degree.

Contexts are now of the form

$$\Delta ::= \epsilon | \Delta, x : A : s$$

In contexts both the type and the kind of a variable are registered.

We have to be careful for non-functional PTS! Here a variable $x$ of type $A$ may have more than one kind $s$. It may be essential for different occurrences of $x$ to have different kinds, so that by fixing the kind for $x$ some terms are no longer typeable. Later an example will be given that shows that for non-functional PTS our new typing relation is not equivalent to the original typing relation.

It turns out that, when deriving the type of a term, we can derive its kind at the same time at little extra cost. Some $\vdash$-inference rules that derive a type $B$ for a term $b$, could also produce the type of this $B$:

$$\frac{}{\Gamma ; x : A : s \vdash x : A}$$

$$\frac{\Gamma , x : A : s \vdash b : B \Gamma , (\forall x : A. B) : s_3}{\Gamma \vdash (\lambda x : A. b) : (\forall x : A. B)}$$

but here the type $s$ of $A$ and the type $s_3$ of $(\forall x : A. B)$ are not passed on in the conclusion. Also, kinds cannot be large terms; by the following lemma the kind of a term is always a sort.

Lemma 3.1. [correctness of types]
If $\Gamma \vdash b : B$ then $\Gamma \vdash B : s$ for some $s \in S$ or $B \in S$.

So the extra amount of information carried around in $\vdash$-derivations in comparison to $\vdash$-derivations is small.

A problem is not all terms that have a type also have a kind. If $\Gamma \vdash b : B$ and $B \in S$, then there may not be a type for $B$, and hence no kind for $b$. This is solved by introducing a new "sort" $\top$, which acts as the type for hitherto untypeable sorts:

Definition 3.2. [$S_T, A_T$]
Given a PTS $(S, A, R)$ we define

$$S_T = S \cup \{\top\}$$

$$A_T = A \cup \{(s : \top) | s \in S \land \neg(\exists r.(s : s') \in A)\}$$

So for all $s \in S$ there is a $s' \in S_T$ such that $(s : s') \in A_T$. For functional PTS this $s'$ is unique, i.e. $A_T$ is a function from $S$ to $S_T$. For functional PTS we write $A_T(s)$ for the $s' \in S_T$ for which $(s : s') \in A_T$.

Convention $s, s_1, s'$, etc. range over $S_T$ (and not just $S$).
Replacing all judgements of the form $\Gamma \vdash b : B$ by judgements $\Delta \vdash b : B : s$ in the PTS inference rules, we get the following typing relation $\Gamma_{\Delta}$. $\Gamma_{\Delta}$ is defined for arbitrary PTS, but only for functional PTS will it be equivalent to the original typing relation $\Gamma$ (hence the subscript $f$ for functional):

**Definition 3.3.** $[\Delta \vdash f_{\Delta} b : B : s]$  

<table>
<thead>
<tr>
<th>(axiom)</th>
<th>$c \in s_{\Gamma}$ if $(s : s') \in A$</th>
</tr>
</thead>
<tbody>
<tr>
<td>(variable)</td>
<td>$\Delta \vdash_A s_1 : s'_1$ $x : A : s_1$</td>
</tr>
<tr>
<td>(weakening)</td>
<td>$\Delta_{\Gamma} b : B : s$ $\Delta_{\Gamma} A : s_1 : s'<em>1$ $\Delta</em>{\Gamma} x : A : s$</td>
</tr>
<tr>
<td>(formation)</td>
<td>$\Delta_{\Gamma} A : s_1 : s'<em>1$ $\Delta</em>{\Gamma} (\Pi x : A, B) : s_2 : B' : s$</td>
</tr>
<tr>
<td>(abstraction)</td>
<td>$\Delta_{\Gamma} A : s_1 : s'<em>1$ $\Delta</em>{\Gamma} (\lambda x : A, b) : (\Pi x : A. B) : s_3$</td>
</tr>
<tr>
<td>(application)</td>
<td>$\Delta_{\Gamma} a : A : s_1$ $\Delta_{\Gamma} B[x := a] : s_2 : s'_2$</td>
</tr>
<tr>
<td>(conversion)</td>
<td>$\Delta_{\Gamma} b : B : s$ $\Delta_{\Gamma} B' : s : s' : B' : s$</td>
</tr>
</tbody>
</table>

Compared with the original typing rules, the major differences are in the abstraction and the application rule. These are discussed below. For all other rules there is a one-to-one correspondence between the premisses in the $\Gamma_{\Delta}$-rule and the corresponding $\Gamma$-rule.

Note that the conversion rule changes the type of a term, but not its kind. This is because in functional PTS the kind of a term is unique (not just unique up to $\beta$-equality).

For functional PTS, $\Gamma_{\Delta}$ is equivalent with $\Gamma$:

**Theorem 3.4.** [soundness and completeness $\Gamma_{\Delta}$]  
For all functional PTS

$$\Gamma \vdash b : B \Rightarrow (\exists s \in S_{\Gamma_{\Delta}}. \tilde{\Gamma}_{\Delta} \vdash b : B : s)$$

$$\Gamma_{\Delta} \vdash b : B : s \Rightarrow (\Delta \vdash \tilde{\Gamma}_{\Delta} b : B : s)$$

where $|\Delta|$ is defined by

$$|\epsilon| = \epsilon 
 |\Delta, x : A : s| = |\Delta|, x : A$$

and $\tilde{\Gamma}$ is defined by

$$\tilde{\Gamma}_{\Delta} x : A = \tilde{\Gamma}, x : A : s \iff \Gamma_{\Delta} \vdash A : s.$$  

**Proof.** See appendix D: lemmas D.1, D.7 and D.8.  

For non-functional PTS there can be terms that are typeable using $\Gamma$, but that are not typeable using $\Gamma_{\Delta}$, as shown in the following example.
Consider the non-functional PTS
\[ S = \{ *, \text{O}_1, \text{O}_2 \}, \quad A = \{ *, \text{O}_1, *, \text{O}_2 \}, \quad R = \{ (\text{O}_1, \text{O}_2, \text{O}_2) \} \]
\[ \vdash (\lambda x : * . x) : (\Pi x : * . x) \text{ is derivable. To derive this we have to derive } \vdash (\Pi x : * . x) : \text{O}_2. \text{ To derive } \vdash (\Pi x : * . x) : \text{O}_2, \text{ the first occurrence of } * \text{ has to be typed } \text{O}_1 \text{ and the second occurrence of } * \text{ has to be typed } \text{O}_2: \]
\[ \frac{\vdash * : \text{O}_1 \quad \vdash * : \text{O}_2}{\vdash (\Pi x : * . x) : \text{O}_2} \quad (\text{O}_1, \text{O}_2, \text{O}_2) \in R \]
Both occurrences of * in \((\Pi x : * . x)\) stem from occurrences of \(x\) in \((\lambda x : * . x)\). If the kind of \(x\) is fixed in a context \(x : * : \text{O}_i\), then both occurrences of * will have the same type \(\text{O}_i\). As a consequence, \((\lambda x : * . x)\) cannot be typed using \(\Gamma\):

\[ \vDash \Gamma \vdash \ast : \text{O}_1 \quad \vDash \Gamma \vdash \ast : \text{O}_2 \quad \vdash (\lambda x : * . x) : (\Pi x : * . x) \]

This type derivation fails because there is no kind \(\text{O}_i\) for \(x\) such that \((\text{O}_i, \text{O}_i, s) \in R\) for some \(s\).

As mentioned earlier, the main differences between \(\Gamma\) and \(\mathcal{F}_\Gamma\) are in the abstraction and the application rule.

The abstraction rule
In the \(\mathcal{F}_\Gamma\)-abstraction rule we save work. Unfolding the \(\Gamma\)-formation rule in the \(\Gamma\)-abstraction rule we get

\[ \frac{\Gamma \vdash A : s_1 \quad \Gamma, x : A \vdash b : B \quad \Gamma \vdash (\Pi x : A. B) : s_3 \quad (s_1, s_2, s_3) \in R}{\Gamma \vdash (\lambda x : A. b) : (\Pi x : A. B)} \]

In this derivation, in order to type \((\lambda x : A. b)\), the terms \(b\), \(A\) and \(B\) are typed.

In the \(\mathcal{F}_\Gamma\)-abstraction rule

\[ \frac{\Delta, x : A : s_1 \quad \Gamma, x : A \vdash b : B : s_2 \quad \Delta \mathcal{F}_\Gamma A : s_1 : e_1}{\Delta \mathcal{F}_\Gamma (\lambda x : A. b) : (\Pi x : A. B) : s_3 \quad (s_1, s_2, s_3) \in R} \]

Here only \(b\) and \(A\) have to be typed. A separate type derivation for \(B\) is no longer needed, because by typing \(b\) we also obtain the type of \(B\). Remember that in section 2.1 it was the premiss \(\Gamma, x : A \vdash B : s_2\) in the abstraction rule that caused the problem in the unsuccessful completeness proof.

The application rule
In the \(\mathcal{F}_\Gamma\)-application rule more work has to be done to produce not only the type but also the kind. The original application rule is

\[ \Gamma \vdash b : (\Pi x : A. B) \]
\[ \Gamma \vdash a : A \]
\[ \Gamma \vdash ba : B[x := a] \]

and the new application rule is

\[ \Delta \mathcal{F}_\Gamma b : (\Pi x : A. B) : s_3 \]
\[ \Delta \mathcal{F}_\Gamma a : A : s_1 \]
\[ \Delta \mathcal{F}_\Gamma B[x := a] : s_2 : s_2' \]
\[ \Delta \mathcal{F}_\Gamma ba : B[x := a] : s_3 \]

The extra work is a type derivation for \(B[x := a]\), which is needed to determine the kind of the application \(ba\). (It turns out that, for a syntax-directed version of \(\mathcal{F}_\Gamma\), the premiss \(\Delta \mathcal{F}_\Gamma B[x := a] : s_2 : s_2'\) causes the same problem in the proof of completeness that we sketched earlier for \(\Gamma\). This is discussed in section 5.)

Fortunately, this extra work can be avoided for a large class of PTS, namely those where given \(s_1\) and \(s_2\) there is at most one \(s_2\) such that \((s_1, s_2, s_3) \in R\). In these PTS the kind of an application is determined by the kind of the function and the kind of its argument.
Definition 3.5. A PTS is called bijective iff it is functional and for all \(s_1, s_2, s_3 \in S\)
\[(s_1, s_2, s_3) \in R \land (s_1, s_2, s_3) \in R \implies s_2 \equiv s'_2\]
So a PTS is bijective iff
\[(s, s') \in A \land (s, s'') \in A \implies s' \equiv s''\]
\[(s_1, s_2, s_3) \in R \land (s_1, s_2, s_3) \in R \implies s_3 \equiv s'_3\]
\[(s_1, s_2, s_3) \in R \land (s_1, s_2, s_3) \in R \implies s_2 \equiv s'_2\]

All functional PTS that only have rules of the form \((s_1, s_2, s_3)\) are bijective. This means that all systems in Barendregt's \(\lambda\)-cube are bijective.

For bijective PTS, the kind of a term is uniquely determined by the kinds of it subterms. As a consequence, the premiss \(\Delta \Gamma \beta B \smallsetminus [x := a] : s_2 : s'_2\) can be omitted in the application rule.

Definition 3.6. \([\Delta \Gamma \beta : B : s]\)
\(\Gamma \beta\) is defined by the same inference rules as \(\Gamma\), except for the application rule.

\[(axiom) \quad \epsilon \Gamma \beta s : s' : A_T(s') \quad if \ (s : s') \in A\]

\[(variable) \quad \frac{\Delta \Gamma \beta A : s_1 : s'_1}{\Delta, x : A : s_1 \ \Gamma \beta x : A : s_1} \quad x \ \text{fresh}\]

\[(weakening) \quad \frac{\Delta \Gamma \beta b : B : s \ \Delta \Gamma \beta A : s_1 : s'_1}{\Delta, x : A : s_1 \ \Gamma \beta b : B : s} \quad x \ \text{fresh}\]

\[(formation) \quad \frac{\Delta \Gamma \beta A : s_1 : s'_1 \ \Delta, x : A : s_1 \ \Gamma \beta b : B : s_2 \ \Delta \Gamma \beta (\Pi x : A. B) : s_3 : A_T(s_3)}{\Delta \Gamma \beta (\Pi x : A. B) : s_3 : A_T(s_3)} \quad if \ (s_1, s_2, s_3) \in R\]

\[(abstraction) \quad \frac{\Delta \Gamma \beta A : s_1 : s'_1 \ \Delta, x : A : s_1 \ \Gamma \beta b : B : s_2}{\Delta \Gamma \beta (\lambda x : A. b) : (\Pi x : A. B) : s_3} \quad if \ (s_1, s_2, s_3) \in R\]

\[(application) \quad \frac{\Delta \Gamma \beta b : B : s \ \Delta \Gamma \beta B' : s' : s' \ B \simeq B'}{\Delta \Gamma \beta b : B' : s} \quad if \ (s_1, s_2, s_3) \in R\]

\[(conversion) \quad \frac{\Delta \Gamma \beta b : B : s \ \Delta \Gamma \beta b : B : s}{\Delta \Gamma \beta b : B : s} \quad if \ (s_1, s_2, s_3) \in R\]

For bijective PTS, \(\Gamma \beta\) is equivalent with \(\Gamma\):

**Theorem 3.7.** [soundness and completeness \(\Gamma \beta\)]

For all bijective PTS
\[\Gamma \vdash b : B \implies (\exists s \in S_T. \hat{\Gamma} \Gamma \beta b : B : s)\]
\[\Delta \Gamma \beta b : B : s \implies |\Delta| \vdash b : B \land (|\Delta| \vdash B : s) \lor (B : s) \in A_T \setminus A\]

where \(|\Delta|\) and \(\hat{\Gamma}\) are defined as in theorem 3.4.

**Proof.** See appendix B: lemmas B.1, B.6, and B.7. \(\Box\)

The proofs of theorems 3.4 and 3.7 are by induction on type derivations, and hence are identical except when the application rule is involved. An alternative to proving theorem 3.7 is proving that for all bijective PTS \(\Delta \Gamma \beta b : B : s \implies \Delta \Gamma \beta b : B : s\).
4 A type-checker for bijective PTS

In this section a syntax-directed version of $\Gamma_b$ is defined, by removing the weakening and conversion rule.

$\Gamma_b$ deals with contexts in the same inefficient way as $\Gamma$ : in every branch of a derivation the context is broken down to check that it is well-formed. To avoid this a notion of well-formedness for contexts is introduced and the original axiom and variable rule are replaced by the following more powerful axiom and variable rules

\[
\text{(axiom)} \quad \Delta \Gamma_{bad} s : s' : A_\tau (s') \quad \text{if } s : s' \in A
\]

\[
\text{(variable)} \quad \Delta, x : A : s, \Delta' \Gamma_{bad} x : A : s
\]

The conversion rule is a source of non-determinism in $\Gamma_b$. It is distributed over the other rules. Conversion is only used to test if

- a type reduces to a sort
- the types of a function and its argument match

The resulting system is syntax-directed: the shape of a term determines which inference rule is used in the last step of its type derivation, and so there is a unique type derivation for a given term. As a consequence, the system provides a type inference algorithm.

Definition 4.1. \([\Delta \Gamma_{bad} b : B : s, WF_{bad} \Delta]\)

For $\Delta \Gamma_{bad} b : B : s$ we have the following inference rules

\[
\text{(axiom)} \quad \Delta \Gamma_{bad} s : s' : A_\tau (s') \quad \text{if } s : s' \in A
\]

\[
\text{(variable)} \quad \Delta, x : A : s, \Delta' \Gamma_{bad} x : A : s
\]

\[\Delta, x : A : s_1 \Gamma_{bad} B : s_2 : s_2' \quad S_2 \to \beta s_2 \]

\[
\frac{\Delta \Gamma_{bad} A : s_1 : s_1' \quad S_1 \to \beta s_1}{\Delta \Gamma_{bad} (\Pi x : A. B) : s_3 : A_\tau (s_3)} \quad \text{if } (s_1, s_2, s_3) \in R \text{ and } x \text{ fresh}
\]

\[\Delta, x : A : s_1 \Gamma_{bad} b : B : s_2 \]

\[\Delta \Gamma_{bad} A : s_1 : s_1' \quad S_1 \to \beta s_1 \quad \text{if } (s_1, s_2, s_3) \in R \text{ and } x \text{ fresh}
\]

\[\Delta \Gamma_{bad} b : C : s_3 \quad C \to \neg \beta (\Pi x : A'. B) \]

\[\frac{\Delta \Gamma_{bad} a : A : s_1 \quad A \simeq A'}{\Delta \Gamma_{bad} b[a : B[x := a]] : s_2} \quad \text{if } (s_1, s_2, s_3) \in R
\]

A context $\Delta$ is $\Gamma_{bad}$-well-formed – written $WF_{bad} \Delta$ – if it can be derived using the rules

\[
\text{(empty)} \quad WF_{bad} \epsilon
\]

\[
\text{(weakening)} \quad WF_{bad} \Delta \Delta \Gamma_{bad} A : s : s' : S \to \beta \Delta \chi, x : A : s
\]

Note that for $\Gamma_{bad}$-derivations the subformula property holds, i.e. the derivation of $\Delta \Gamma_{bad} b : B : s$ only contains type-kind derivations for subterms of $b$.

Theorem 4.2. [soundness and completeness $\Gamma_{bad}$]

For all bijective PTS:

\[
\Delta \Gamma_{bad} b : B : s \land WF_{bad} \Delta \implies \Delta \Gamma_b b : B : s
\]

\[
\Delta \Gamma_{bad} b : B : s \implies WF_{bad} \Delta \land (\exists B' \simeq B. \Delta \Gamma_{bad} b : B' : s)
\]

Proof. See appendix C: lemmas C.1, C.5 and C.6.
Joining theorems 3.7 and 4.2 yields

**Corollary 4.3.** [soundness and completeness of \( \Gamma \) w.r.t. \( \vdash \)]

For all bijective PTS:

\[
\Delta \vdash b : B : s \land WF_{\text{bsd}} \Delta \implies (\Delta \vdash b : B \land (\Delta \vdash B : s \lor (B : s) \in A_T \setminus A))
\]

\[
\Gamma \vdash b : B \implies (\exists s \in B_T, B' \succeq B. \Gamma \vdash b : B' : s)
\]

It is easy to define an algorithm which, given a context \( \Delta \) and a term \( a \), checks \( WF_{\text{bsd}} \Delta \) and tries to constructs the type derivation for \( a \) in context \( \Delta \), thus finding the type (and the kind) of \( a \). This does require strong normalisation of \( \beta \)-reduction for types, i.e.

\[
\Gamma \vdash a : A \Rightarrow A \text{ is } \beta\text{-strongly normalising}
\]

(or, equivalently, \( WF_{\text{bsd}} \Delta \land \Delta \vdash a : A : s \Rightarrow A \text{ is } \beta\text{-strongly normalising} \)). This is needed to ensure that \( \beta \) normal forms and weak head normal forms of types can be computed, and that convertibility of types is decidable, so that the premises \( S_i \rightarrow \beta s_i, C \rightarrow_{\text{wh}} (\Pi x : A. B) \) and \( A \simeq A' \) are decidable.

The algorithm has to choose a correct order in which to check the different premisses of the rules, so that it nevers attempts to construct a type derivation in a context which may be incorrect.

If \( \Delta \vdash b : B : s \) and not \( WF_{\text{bsd}} \Delta \), then we do not know if \( A \) is strongly normalising. This means that in the formation and abstraction rules the premisses \( \Delta \vdash A : S_1 : s' \) and \( S_1 \rightarrow \beta s_1 \) have to be checked first, and in the the weakening rule the premiss \( WF_{\text{bsd}} \Delta \) has to be checked first.

5 **Functional PTS**

For functional PTS that are not bijective a syntax-directed system can be defined in the same way as was done in the previous section, this time taking \( \Gamma \) instead of \( \Gamma_{\text{bsd}} \) as the starting point.

**Definition 5.1.** \([\Delta \vdash b : B : s, WF_{\text{bsd}} \Delta] \)

\( \Gamma_{\text{bsd}} \) and \( WF_{\text{bsd}} \) are defined as \( \Gamma_{\text{bsd}} \) and \( WF_{\text{bsd}} \), except for the application rule, where we have the following rule instead

\[
\begin{align*}
\Delta & \vdash b : C : s_3 \\
\Delta & \vdash a : A : s_1 \\
A & \simeq A' \\
\Gamma & \vdash_{\Gamma_{\text{bsd}}} B[x := a] : s_2 : s_2' \\
\Gamma & \vdash_{\Gamma_{\text{bsd}}} ba : B[x := a] : s_2 : s_2'
\end{align*}
\]

Soundness of this system can be proved for all functional PTS:

\[ \Delta \vdash_{\Gamma_{\text{bsd}}} b : B : s \land WF_{\text{bsd}} \implies \Delta \vdash_{\Gamma} b : B : s. \]

However, proving completeness for this system,

\[ \Delta \vdash_{\Gamma} b : B : s \implies (\exists B' \simeq B. \Delta \vdash_{\Gamma_{\text{bsd}}} b : B' : s), \]

is a problem. In fact, we now have the same problem with the premiss \( \Gamma \vdash_{\Gamma} B[x := a] : s_2 : s_2' \) in the application rule that we sketched in section 2.1 for the premiss \( \Gamma \vdash (\Pi x : A. B) : s \) in the abstraction rule.
6 Related work

Other type-checking algorithms for Pure Type Systems all involve a way of avoiding the premiss \( \Gamma, x : A \vdash B : s_2 \) in the abstraction rule

\[
\Gamma \vdash A : s_1 \quad \Gamma, x : A \vdash b : B \quad \Gamma, x : A \vdash B : s_2 \quad \frac{}{\Gamma \vdash (\lambda x : A, b) : (\Pi x : A, B)} \quad \text{if } (s_1, s_2, s_3) \in R
\]

One possibility is to consider only PTS where \( R \) is such a large subset of \( S \times S \times S \) that we do not have to know a type \( s_2 \) of \( B \) to decide if \((\Pi x : A, B)\) can be formed. In [Pol92] Pollack gives a sound and complete type inference algorithm for all semi-full PTS, which is a generalisation of the type inference algorithm used in Huet's Constructive Engine for the Calculus of Constructions. A PTS is semi-full if

\[
\forall s_1 \quad (\exists s_2, s_3 (s_1, s_2, s_3) \in R) \implies (\forall s_2 \exists s_3 (s_1, s_2, s_3) \in R)
\]

For these PTS, only a type \( s_1 \) of \( A \) and a type \( B \) of \( b \) - but not the type of this \( B \) - have to be known to decide if the \( \lambda \)-abstraction \((\lambda x : A, b)\) is allowed: the rule

\[
\Gamma \vdash A : s_1 \quad \Gamma, x : A \vdash b : B \quad B \notin \{s \in S \mid \exists s' (s : s') \in A\} \quad \frac{}{\Gamma \vdash (\lambda x : A, b) : (\Pi x : A, B)} \quad \text{if } (s_1, s_2, s_3) \in R
\]

is equivalent with the abstraction rules given above.

For example, for the Calculus of Constructions, the PTS with

\[
S = \{*, \Box\} \quad A = \{(* : \Box)\} \quad R = \{(s_1, s_2, s_3) \mid s_1, s_2 \in S\}
\]

this abstraction rule becomes

\[
\Gamma \vdash A : s_1 \quad \Gamma, x : A \vdash b : B \quad B \not\equiv \Box \quad \frac{}{\Gamma \vdash (\lambda x : A, b) : (\Pi x : A, B)}
\]

which is in fact the original abstraction rule given in [CH88] for the Calculus of Constructions.

Jutting proved soundness and completeness for a type inference algorithm for all functional PTS [vBJ92]. He considers an abstraction rule of the form

\[
\Gamma \vdash A : s_1 \quad \Gamma, x : A \vdash b : B \quad \Gamma, x : A \vdash B : s_2 \quad \frac{}{\Gamma \vdash (\lambda x : A, b) : (\Pi x : A, B)} \quad \text{if } (s_1, s_2, s_3) \in R
\]

where \( \vdash \) is a typing relation which is more liberal than \( \vdash \). This result has been extended to all PTS in [vBJMP93].

\( F_{bad} \) does not give a type inference algorithm for all PTS, but it has the advantage that it is closer to the original PTS type derivation rules than Jutting's algorithm. This makes it easy to incorporate other type constructors, as is sketched in the next section.
7 Conclusions

For bijective PTS the following equivalences have been proved
\[ \vdash \iff \vdash_{b} \iff \vdash_{bsd} \]

For functional PTS we have the following relationships between the different systems
\[ \vdash \iff \vdash_{f} \iff \vdash_{bsd} \]

The steps leading from the original typing relation \( \vdash \) to the syntax-directed \( \vdash_{bsd} \) are

1. from \( \vdash \) to \( \vdash_{b} \): type-kind derivations instead of type derivations, i.e. judgements of the form
   \[ x_{1} : A_{1} : s_{1}, \ldots, x_{n} : A_{n} : s_{n} \vdash a : A : s \]
   instead of the usual judgements of the form
   \[ x_{1} : A_{1}, \ldots, x_{n} : A_{n} \vdash a : A \]

2. from \( \vdash_{b} \) to \( \vdash_{bsd} \):
   - making the weakening rule redundant, by introducing a notion of well-formedness for contexts and more powerful axiom and variable rules, and
   - getting rid of the conversion rule by distributing it over the other rules.

In the same way sound and complete type-checkers for PTS’s extended with more primitives, such as Cartesian product types, disjoint sum types, \( \Sigma \) or existential types, can be found. For all these extensions we run into the same problem as for the \( \Pi \)-types, namely that we do not know how to prove completeness. By considering type-kind derivations this problem is avoided.

For example, for Cartesian products the formation and introduction rules are

\[
\begin{align*}
\text{formation} & : \Gamma \vdash A : s_{1}, \Gamma \vdash B : s_{2} \quad \text{if } (s_{1}, s_{2}, s_{3}) \in R_{x} \\
\text{introduction} & : \Gamma \vdash a : A, \Gamma \vdash b : B \quad \Gamma \vdash A \times B : s_{3} \\
\end{align*}
\]

where \( R_{x} \subseteq S^{3} \) controls the formation of Cartesian products. If we want to prove completeness of a type-checker for PTS extended with products, the premiss \( \Gamma \vdash A \times B : s_{3} \) in the \( x \)-introduction rule poses the same problem as the premiss \( \Gamma \vdash (\Pi x : A. B) : s_{3} \) in the abstraction rule. Fortunately, this premiss is exactly the one that can be omitted in the \( x \)-introduction rule for type-kind derivations:

\[
\begin{align*}
\text{introduction} & : \Delta \vdash a : A, \Delta \vdash b : B \quad \text{if } (s_{1}, s_{2}, s_{3}) \in R_{x} \\
\end{align*}
\]

However, the restriction of "bijectivity" has to be extended to \( R_{x} \): the kind of a pair \( (a, b) \) has to be uniquely determined by the kinds of of the two components, i.e.

\[ (s_{1}, s_{2}, s_{3}) \in R_{x} \land (s_{1}, s_{2}, s_{3})' \in R_{x} \implies s_{3} \equiv s_{3}' \]

and the kinds of the first and second projections of a pair have to be uniquely determined by the kind of that pair, i.e.

\[ (s_{1}, s_{2}, s_{3}) \in R_{x} \land (s_{1}', s_{2}', s_{3}) \in R_{x} \implies s_{1} \equiv s_{1}' \land s_{2} \equiv s_{2}' \]

Under these restrictions, removing the weakening and conversion rules as was done for \( \vdash_{b} \) produces a sound and complete type-checker for bijective PTS’s with Cartesian products. This includes all bijective PTS with \( R_{x} \subseteq \{(s, s, s) \mid s \in S\} \), the most sensible choices for \( R_{x} \).
APPENDICES : proofs of equivalences

Most proofs are uneventful proofs by induction on derivations. The most interesting parts are in the proofs of lemmas B.1 and B.6, the cases where the last step is the application rule.

A Properties of PTS

Convention $\alpha$-convertible terms are identified.

The following lemmas will be needed. With the exception of lemma A.7 they are all basic properties of PTS given in [Bar92].

Lemma A.1. [subject reduction for $\vdash : \text{SR}_\alpha$
If $\Gamma \vdash b : B$ and $b \rightarrow_\beta b'$, then $\Gamma \vdash b' : B$.

Lemma A.2. [start lemma for $\vdash$
(i) If $\Gamma \vdash b : B$ and $(s : s') \in A$, then $\Gamma \vdash s : s'$.
(ii) If $\Gamma, x : A, \Gamma' \vdash b : B$, then $\Gamma, x : A, \Gamma' \vdash x : A$.

Lemma A.3. [$\Pi$-generation lemma for $\vdash$
Suppose $\Gamma \vdash (\Pi x : A. B) : s_3$.
Then $\Gamma \vdash A : s_1$ and $\Gamma, x : A \vdash B : s_2$ for some $(s_1, s_2, s_3) \in R$.

Lemma A.4. [sort-generation lemma for $\vdash$
Suppose $\Gamma \vdash s : A$.
Then $A \simeq s'$ for some $(s : s') \in A$.

Lemma A.5. [substitution lemma for $\vdash$
Suppose $\Gamma, x : C, \Gamma' \vdash b : B$ and $\Gamma \vdash c : C$.
Then $\Gamma, \Gamma'[x := c] \vdash b[x := c] : B[x := c]$.

Lemma A.6. [unicity of types for $\vdash : \text{UT}_\alpha$
For functional PTS: if $\Gamma \vdash b : B$ and $\Gamma \vdash b : B'$, then $B \simeq B'$.

Lemma A.7.
Suppose $A' \simeq A$ and $\Gamma \vdash A' : C$.
Then $(A : s) \not\subseteq A' \setminus A$.

Proof. Suppose towards a contradiction that $(A : s) \in A' \setminus A$ (so $s = \top$).
Then $A$ is a sort, so $A' \rightarrow_\beta A$, and by $\text{SR}_\alpha$ it follows from $\Gamma \vdash A' : C$ that $\Gamma \vdash A : C$.
By the lemma A.4 there then is a sort $s'$ such that $s' \simeq C$ and $(A : s') \in A$.
But $(A : s) \in A' \setminus A$, and we have a contradiction. \qed
B  Theorem 3.7: $\vdash \iff \vdash b$

We now prove theorem 3.7: for all bijective PTS

\[(3.7.1) \quad \Gamma \vdash b : B \Rightarrow (\exists s \in S^{\Gamma} : \tilde{\Gamma} \vdash b : s)\]
\[(3.7.2) \quad \Delta \vdash b : B : s \Rightarrow (\exists \Delta \vdash b : B \land (\exists \Delta \vdash B : s \vee (B : s) \in A^{\Gamma} \setminus A))\]

where $|\Delta|$ and $\tilde{\Gamma}$ are defined as in theorem 3.4.

The first part follows from lemmas B.6 and B.7; the second part is proved in the next lemma.

**Lemma B.1.** For all bijective PTS

if $\Delta \vdash b : B : s$ then

(i) $|\Delta| \vdash b : B$, and

(ii) $|\Delta| \vdash B : s \vee (B : s) \in A^{\Gamma} \setminus A$.

**Proof.** By induction on the derivation of $\Delta \vdash b : B : s$. Last step:

**Axiom.** The last step in the derivation in $\Gamma \vdash s : s' : A^{\Gamma}(s')$ where $s : s' \in A$.

To prove:

(i) $\exists s : s'$

(ii) $\exists s : A^{\Gamma}(s') \vee (s' : A^{\Gamma}(s')) \in A^{\Gamma} \setminus A$

$s : s' \in A$, so $\exists s : s'$.

If $(s' : A^{\Gamma}(s')) \notin A^{\Gamma} \setminus A$ then $(s' : A^{\Gamma}(s')) \in A$ and then $\exists s' : A^{\Gamma}(s')$.

**Variable.** The last step in the derivation is

$$
\frac{\Delta \vdash b : B : s}{\Delta, x : A : s_1 \vdash b : B : s}
$$

To prove:

(i) $|\Delta|, x : A \vdash x : A$

(ii) $|\Delta|, x : A \vdash A : A_1 \vee (A : A_1) \in A^{\Gamma} \setminus A$

By the IH $|\Delta| \vdash A : s_1$. The $\vdash$-variable rule gives (i):

$$
\frac{|\Delta| \vdash A : s_1}{|\Delta|, x : A \vdash x : A}
$$

The $\vdash$-weakening rule gives (ii):

$$
\frac{|\Delta| \vdash A : s_1}{|\Delta|, x : A \vdash A : s_1}
$$

**Weakening.** The last step in the derivation is

$$
\frac{\Delta \vdash b : B \quad \Delta \vdash b : A : s_1}{\Delta, x : A : s_1 \vdash b : B : s}
$$

To prove:

(i) $|\Delta|, x : A \vdash b : B$

(ii) $|\Delta|, x : A \vdash b : B \vee (B : s) \in A^{\Gamma} \setminus A$

By the IH $|\Delta| \vdash A : s_1$ and $|\Delta| \vdash b : B$ so the $\vdash$-weakening rule gives (i):

$$
\frac{|\Delta| \vdash b : B \quad |\Delta| \vdash A : s_1}{|\Delta|, x : A \vdash b : B}
$$

By the IH $|\Delta| \vdash A : s_1$ and $(|\Delta| \vdash B : s \vee (B : s) \in A^{\Gamma} \setminus A)$.

If $(B : s) \notin A^{\Gamma} \setminus A$ then $|\Delta| \vdash B : s$ and the $\vdash$-weakening rule gives (ii)

$$
\frac{|\Delta| \vdash B : s \quad |\Delta| \vdash A : s_1}{|\Delta|, x : A \vdash B : s}
$$
Conversion. The last step in the derivation is

\[
\frac{\Delta \vdash b : B \quad \Delta \vdash b : B'}{\Delta \vdash b : B'}
\]

To prove:

(i) \( \Delta \vdash b : B \)

(ii) \( \Delta \vdash B' : s' \lor (B' : s') \in A \neg A \)

By the IH \( \Delta \vdash B' : s', \) so (ii).

By the IH \( \Delta \vdash b : B \) and \( \Delta \vdash B' : s', \) so the \( \vdash \)-conversion rule gives (i):

\[
\frac{\Delta \vdash b : B \quad \Delta \vdash B' : s}{\Delta \vdash B' : s}
\]

Formation. The last step in the derivation is

\[
\frac{\Delta \vdash A : s_1 \quad \Delta, x : A \vdash b : s_2}{\Delta \vdash (\forall x : A. b) : s_3 \quad (s_1, s_2, s_3) \in R}
\]

To prove:

(i) \( \Delta \vdash (\forall x : A. B) : s_3 \)

(ii) \( \Delta \vdash s_3 : A \neg s_3 \lor (s_3 : A \neg s_3) \in A \neg A \)

By the IH \( \Delta \vdash A : s_1 \) and \( \Delta \vdash x : A \vdash B : s_2, \) so the \( \vdash \)-formation rule gives (i):

\[
\frac{\Delta \vdash A : s_1 \quad \Delta \vdash x : A \vdash B : s_2}{\Delta \vdash (\forall x : A. B) : s_3}
\]

\((s_3 : A \neg (s_3)) \in A \) or \((s_3 : A \neg (s_3)) \in A \neg A \).

If \((s_3 : A \neg (s_3)) \in A \neg A \) then (ii).

If \((s_3 : A \neg (s_3)) \in A \) then by the \( \vdash \)-start lemma \((A.2) \) \( \Delta \vdash s_3 : A \neg (s_3) \) and hence (ii).

Abstraction. The last step in the derivation is

\[
\frac{\Delta \vdash A : s_1 \quad \Delta, x : A \vdash b : s_2}{\Delta \vdash (\lambda x : A. b) : (\forall x : A. B) : s_3 \quad (s_1, s_2, s_3) \in R}
\]

Clearly \((\forall x : A. B) : s_3 \notin A \neg A, \) so to prove:

(i) \( \Delta \vdash (\lambda x : A. b) : (\forall x : A. B) \)

(ii) \( \Delta \vdash (\forall x : A. B) : s_3 \)

By the IH \( \Delta \vdash x : A \vdash B : s_2 \) \( \Delta \vdash \vdash A : s_1 \).

Also by the IH \( \Delta \vdash x : A \vdash B : s_2 \lor (B : s_2) \in A \neg A \). If \((B : s_2) \in A \neg A \) then \( s_2 \equiv T. \) But \((s_1, s_2, s_3) \in R \subseteq A \), so \( s_2 \not\equiv T. \) Hence \( \Delta \vdash x : A \vdash B : s_2. \)

The \( \vdash \)-formation rule gives (i):

\[
\frac{\Delta \vdash A : s_1 \quad \Delta \vdash x : A \vdash B : s_2}{\Delta \vdash (\lambda x : A. b) : (\forall x : A. B) : s_3}
\]

and then the \( \vdash \)-abstraction rule gives (ii):

\[
\frac{\Delta \vdash x : A \vdash b : B \quad \Delta \vdash (\forall x : A. B) : s_3}{\Delta \vdash (\lambda x : A. b) : (\forall x : A. B) : s_3}
\]
Application. The last step in the derivation is

\[
\Delta \vdash b : ((\Pi x : A. B) : s_3) \\
\Delta \vdash a : A : s_1 \\
\Delta \vdash BA[x := a] : s_2
\]

for some \((s_1, s_2, s_3) \in R\).

To prove:

(i) \(\Delta \vdash ba : B[x := a]\)

(ii) \(\Delta \vdash B[x := a] : s_2 \lor (B[x := a] : s_2) \in A_T \setminus A\)

By the IH

\[
\Delta \vdash a : A \\
\Delta \vdash b : ((\Pi x : A. B))
\]

so the \(\vdash\) application rule gives (i):

\[
\frac{\Delta \vdash a : A}{\Delta \vdash b : (\Pi x : A. B)}
\]

By the IH also

\[
\Delta \vdash A : s_1 \lor (A : s_1) \in A_T \setminus A \\
\Delta \vdash B[x := a] : s_2 \lor (B[x := a] : s_2) \in A_T \setminus A
\]

since clearly \(((\Pi x : A. B) : s_3) \notin A_T \setminus A\). Then by the \(\Pi\)-generation lemma for \(\vdash (A.3)\) it follows from (4) that

\[
\Delta \vdash A : t_1 \\
\Delta \vdash B[x := a] : t_2
\]

for some \((t_1, t_2, s_3) \in R\). By lemma A.7 it follows from (3) and (5) that \(\Delta \vdash A : s_1\). By \(UT\) then \(s_1 \equiv t_1\), and since the PTS is bijective, \(s_2 \equiv t_2\).

Finally, by the \(\vdash\)-substitution lemma (A.5) it follows from (1) and (6) that \(\Delta \vdash B[x := a] : s_2\), and hence (ii).

To prove (3.7.1) — "\(\vdash \Rightarrow \vdash_b\)" — we need the \(\Pi\)-generation lemma for \(\vdash_b\) (lemma B.5) and unicity of types for \(\vdash_b\).

Lemma B.2. [unicity of types for \(\vdash_b : UT\)]

For bijective PTS:

(i) if \(\Delta \vdash b : B : s\) and \(\Delta \vdash b : B' : s'\) then \(B \simeq B'\) and \(s \equiv s'\).

(ii) if \(\Delta \vdash b : B : s\) and \(\Delta \vdash B : S : s'\) then \(s \equiv s'\).

Proof. (i) Suppose \(\Delta \vdash b : B : s\) and \(\Delta \vdash b : B' : s'\).

Then by the previous lemma \(\Delta \vdash b : B\) and \(\Delta \vdash b : B'\), so by \(UT\) \(B \simeq B'\). Also, by the previous lemma

\[
\Delta \vdash B : s \lor (B : s) \in A_T \setminus A \\
\Delta \vdash B' : s' \lor (B' : s') \in A_T \setminus A
\]

If \(\Delta \vdash B : s\), then by lemma A.7 \(\Delta \vdash B' : s'\) and by \(SR\) and \(UT\) \(s \equiv s'\).

In the same way, if \(\Delta \vdash B' : s'\), then also \(s \equiv s'\).

Finally, if both \((B : s) \in A_T \setminus A\) and \((B' : s') \in A_T \setminus A\) then \(s \equiv s' \equiv T\).

(ii) Suppose \(\Delta \vdash b : B : s\) and \(\Delta \vdash B : B' : s'\).

Then by the previous lemma

\[
\Delta \vdash B : s \lor (B : s) \in A_T \setminus A \\
\Delta \vdash B : S
\]

It then follows from lemma A.7 that \(\Delta \vdash B : s\), and hence by \(UT\) \(s \simeq S\).
For the $I$-generation lemma the thinning lemma is required, which in turn requires the following start lemma.

**Lemma B.3.** [start lemma for $I-b$]
If $\Delta \vdash b : B : s$ and $(s : s') \in A$, then $\Delta \vdash b : s : A \uparrow (s')$.
If $\Delta, x : A : s$, $\Delta' \vdash b : B : s$ then $\Delta, x : A : s$, $\Delta' \vdash b : A : s$.

**Proof.** Induction on the derivation of $\Delta \vdash b : B : s$ and $\Delta, x : A : s$, $\Delta' \vdash b : B : s$.

**Lemma B.4.** [thinning lemma for $I-b$]
Suppose $\Delta' \vdash b : B : s$, $\Delta' \subseteq \Delta$ and $\Delta \vdash a : A$.
Then $\Delta \vdash a : A : s$.

**Proof.** Induction on the derivation of $\Delta \vdash a : A : s$. The start lemma is used if the last rule applied is the axiom or variable rule.

**Lemma B.5.** [II-generation lemma for $I-b$]
Let $\Delta \vdash (\Pi x : A. B) : s_3 : s_2$. Then there are $s_1$, $s_1'$, $s_2$ and $s_2'$ such that
$(s_1, s_2, s_3) \in \mathcal{R}$, $\Delta \vdash A : s_1 : s_1'$ and $\Delta, x : A : s_1 \vdash b : B : s_2 : s_2'$.

**Proof.** Any derivation of $\Delta \vdash (\Pi x : A. B) : s_3 : s_2'$ ends with the formation rule followed by zero or more uses of the conversion rule and/or the weakening rule:

$$
\begin{array}{c}
\Delta', x : A : s_1 \vdash b : s_2 : s_2' \\
\Delta' \vdash b : s_2 : s_2' \\
\Delta \vdash (\Pi x : A. B) : s_3 : s_2' \\
\end{array}
$$

(weakening/conversion)

where $(s_1, s_2, s_3) \in \mathcal{R}$.

The weakening rule does not affect the type $s$ of $(\Pi x : A. B)$, and the conversion rule only $\beta$-converts it. So $s_3 \equiv s$, and since $s$ and $s_3$ are both sorts, $s_3 \equiv s$.

$\Delta' \subseteq \Delta$, so by the thinning lemma for $I-b$: $\Delta, x : A : s_1 \vdash b : B : s_2 : s_2'$ and $\Delta \vdash A : s_1 : s_1'$.

To prove (3.7.1) for all bijective PTS

$$
\Gamma \vdash b : B \Rightarrow (\exists s \in S_\tau. \hat{\Gamma} \vdash b : B : s)
$$

where $\hat{\Gamma}$ is defined by

$$
\begin{array}{c}
\Gamma, \overline{\cdot} = \epsilon \\
\Gamma, x : A = \hat{\Gamma}, x : A : s \quad \text{if } \Gamma \vdash A : s
\end{array}
$$

we first prove

**Lemma B.6.** For bijective PTS

$$
\Gamma \vdash b : B \Rightarrow (\exists s \in S_\tau. \overline{\Gamma} \vdash b : B : s)
$$

where $\overline{\Gamma}$ is defined by

$$
\begin{array}{c}
\Gamma, \overline{\cdot} = \epsilon \\
\Gamma, x : A = \overline{\Gamma}, x : A : s \quad \text{if } \Gamma \vdash A : s
\end{array}
$$

By $UT_{\hat{\Gamma}}$(lemma B.2) this defines a unique $\overline{\Gamma}$. We have to use $\overline{\Gamma}$ instead of $\hat{\Gamma}$ as defined in theorem 3.4 for the proof to run smoothly. In the next lemma lemmas B.1 and B.6 will be used to prove that $\hat{\Gamma}$ and $\overline{\Gamma}$ are the same.
Proof. By induction on the derivation of \( \Gamma \vdash b : B \).

**Axiom.** So \( x \vdash s : s' \), where \( s : s' \in A \). Then by the \( \text{I-b-axiom} \) rule \( \Gamma \vdash b : A \tau (s') \).

**Variable.** The last step in the derivation is

\[
\frac{\Gamma \vdash A : s_1}{\text{I}_x \vdash x : A : s_1}
\]

To prove : \( (\exists s \in S_T. \bar{T}, x : A \vdash \text{I}_b, \bar{b} : b : s) \).

By the IH there is a \( s_1' \) such that \( \bar{T}, x : A \vdash \text{I}_b, A : s_1 : s_1' \).

Then \( \bar{T}, x : A \equiv \bar{T}, x : A : s_1 \), and the \( \text{I-b-variable rule} \) gives

\[
\frac{\bar{T}, x : A : s_1}{\bar{T}, x : A : s_1 : s_1'}
\]

**Weakening.** The last step in the derivation is

\[
\frac{\Gamma \vdash b : B \quad \Gamma \vdash A : s_1}{\bar{T}, x : A : \text{I}_b, \bar{b} : b : B}
\]

To prove : \( (\exists s \in S_T. \bar{T}, x : A \vdash \text{I}_b, \bar{b} : b : s) \).

By the IH there are \( s \) and \( s_1' \) such that \( \bar{T}, x : A \vdash \text{I}_b, b : B : s \) and \( \bar{T}, x : A \vdash \text{I}_b, A : s_1 : s_1' \).

Then \( \bar{T}, x : A \equiv \bar{T}, x : A : s_1 \), and the \( \text{I-b-weakening rule} \) gives

\[
\frac{\bar{T}, x : A : s_1}{\bar{T}, x : A : s_1 : s_1'}
\]

**Conversion.** The last step in the derivation is

\[
\frac{\Gamma \vdash b : B \quad \Gamma \vdash b' : s' \quad B \simeq B'}{\bar{T}, x : A \vdash \text{I}_b, (\Pi x : A. B) : s'' : B}
\]

To prove : \( (\exists s \in S_T. \bar{T}, x : A \vdash \text{I}_b, (\Pi x : A. B) : s) \).

By the IH there are \( s \) and \( s_1' \) such that \( \bar{T}, x : A \vdash \text{I}_b, b : B : s \) and \( \bar{T}, x : A \vdash \text{I}_b, B' : s' : s'' \). To use the \( \text{I-b-conversion rule} \) we have to prove \( s' \equiv s \).

By lemma B.1 (\( \Gamma \vdash B : s \lor (B : s) \in A \tau (A) \)). Since also \( \Gamma \vdash B' : s' \), it follows by lemma A.7 that \( \Gamma \vdash B : s' \). Then by \( \text{SR}(\text{lemma A.1}) \) a common reduct of \( B \) and \( B' \) has both type \( s \) and \( s' \), so by \( \text{UT}(\text{lemma A.6}) \) \( s' \equiv s \).

The \( \text{I-b-conversion rule} \) now gives

\[
\frac{\bar{T}, x : A : s_1 \quad \bar{T}, x : A \vdash \text{I}_b, B' : s' \quad B \simeq B'}{\bar{T}, x : A \vdash \text{I}_b, (\Pi x : A. B) : s'' : B}
\]

**Formation.** The last step in the derivation is

\[
\frac{\Gamma \vdash A : s_1 \quad \Gamma \vdash x : A \vdash B : s_2 \quad s_1, s_2, s_3 \in R}{\bar{T}, x : (\Pi x : A. B) : s_3 : s_2}
\]

To prove : \( (\exists s \in S_T. \bar{T}, x : A \vdash \text{I}_b, (\Pi x : A. B) : s) \).

By the IH \( \bar{T}, x : A \vdash \text{I}_b, A : s_1 : s_1' \) and \( \bar{T}, x : A \vdash \text{I}_b, B : s_2 : s_2' \) for some \( s_1' \) and \( s_2' \).

Then \( \bar{T}, x : A \equiv \bar{T}, x : A : s_1 \), and the \( \text{I-b-formation rule} \) gives

\[
\frac{\bar{T}, x : A : s_1 \quad \bar{T}, x : A : s_1 \vdash \text{I}_b, B : s_2 : s_2'}{\bar{T}, x : (\Pi x : A. B) : s_2 : s_3}
\]
Abstraction. The last step in the derivation is
\[
\Gamma, x : A \vdash b : B \quad \Gamma \vdash (\Pi x : A. B) : s_3
\]
\[
\Gamma \vdash (\lambda x : A. b) : (\Pi x : A. B)
\]
To prove: \((\exists s \in S_r. \overline{T} F_b (\lambda x : A. b) : (\Pi x : A. B) : s)\).

By the IH there are \(s_2\) and \(s'_3\) such that
\[
\overline{T} F_b b : B : s_2 \quad (1)
\]
\[
\overline{T} F_b (\Pi x : A. B) : s_3 : s'_3 \quad (2)
\]
By the \(\Pi\)-generation lemma for \(F_b\) (lemma B.5) it follows from (2) that there are \(s_1, s'_1, t_2\) and \(t'_2\) with \((s_1, t_2, s_3) \in R\) such that
\[
\overline{T} F_b A : s_1 : s'_1 \quad (3)
\]
\[
\overline{T}, x : A : s_1 F_b b : B : t_2 : t'_2 \quad (4)
\]
From (3) it follows that \(\overline{T}, x : A \equiv \overline{T}, x : A : s_1\).

By UT\(\alpha\) (lemma B.2) it follows from (1) and (4) that \(t_2 \equiv s_2\).

Now the \(F_b\)-abstraction rule gives
\[
\overline{T} F_b A : s_1 : s'_1 \quad \overline{T}, x : A : s_1 F_b b : B : s_2 \quad \overline{T} F_b (\lambda x : A. b) : (\Pi x : A. B) : s_3
\]
Application. The last step in the derivation is
\[
\Gamma \vdash b : (\Pi x : A. B) \quad \Gamma \vdash a : A
\]
\[
\Gamma \vdash ba : B[x := a] : s.
\]
To prove: \((\exists s \in S_r. \overline{T} F_b ba : B[x := a] : s)\).

By the IH there are \(s_3\) and \(s_1\) such that
\[
\overline{T} F_b a : A : s_1 \quad (1)
\]
\[
\overline{T} F_b b : (\Pi x : A. B) : s_3 \quad (2)
\]
If there is an \(s_2\) such that \((s_1, s_2, s_3) \in R\), then we can use the \(F_b\)-application rule to derive
\[
\overline{T} F_b ba : B[x := a] : s_2 \text{ from (1) and (2)}.
\]
So, to prove: \(\exists_{s_2}(s_1, s_2, s_3) \in R\).

By lemma B.1 \((F_b \Rightarrow \vdash)\) it follows from (1) and (2) that
\[
\Gamma \vdash A : s_1 \lor (A : s_1) \in A \setminus \mathcal{A} \quad (3)
\]
\[
\Gamma \vdash (\Pi x : A. B) : s_3 \quad (4)
\]
since clearly \((\Pi x : A. B) : s_3 \not\in A \setminus \mathcal{A}\).

By the \(\Pi\)-generation lemma for \(\Gamma (A.3)\) it follows from (4) that
\[
\Gamma \vdash A : t_1 \quad (5)
\]
\[
\Gamma, x : A \vdash B : s_2 \quad (6)
\]
for some \((t_1, s_2, s_3) \in R\). If we can prove \(s_1 \equiv t_2\), then we are done.

By lemma A.7 it follows from (3) and (5) that \(\Gamma \vdash A : s_1\). By UT\(\alpha\) (lemma A.6) then \(t_1 \equiv s_1\).
The two ways to extend \( \vdash \)-contexts to \( \vdash_b \)-contexts defined in theorem 3.4 and the previous lemma are the same:

Lemma B.7. \( \overline{\Gamma} \equiv \hat{\Gamma} \)

Proof. Induction on \( \Gamma \). The base case \( \Gamma \equiv \epsilon \) is trivial.
Suppose \( \Gamma \equiv \Gamma', x : A \). Then
\[
\Gamma', x : A \equiv \hat{\Gamma}', x : A : s \quad \text{if} \quad \Gamma \vdash A : s
\]
\[
\overline{\Gamma}', x : A \equiv \overline{\hat{\Gamma}}', x : A : s \quad \text{if} \quad \exists_{\psi} \overline{\Gamma} \vdash_b A : s'
\]
By the IH \( \overline{\Gamma} \equiv \hat{\Gamma} \), and by lemmas B.1 and B.6
\[
\Gamma \vdash A : s \iff \exists_{\psi} \overline{\Gamma} \vdash_b A : s'
\]
\( \square \)
C  Theorem 4.4: $\Gamma_{bsd} \iff \Gamma_{bsd}$

We now prove theorem 4.2: for all bijective PTS

$$\Delta \Gamma_{bsd} b : B : s \land \text{Wf}_{bsd} \Delta \iff \Delta \Gamma_{bsd} b : B : s$$

**Lemma C.1.** For bijective PTS

$$\Delta \Gamma_{bsd} b : B : s \Rightarrow (\exists B' \simeq B. \Delta \Gamma_{bsd} b : B' : s)$$

**Proof.** By induction on the derivation of $\Delta \Gamma_{bsd} b : B : s$.

**Last step:**

**Axiom, Variable.** The conclusions of the $\Gamma_{bsd}$-axiom and variable rule are instances of the corresponding $\Gamma_{bsd}$-inference rules, so the induction step is trivial.

**Conversion.** The last step in the derivation is

$$\Delta \Gamma_{bsd} b : B : s$$

To prove: $\exists B'' \simeq B'. \Delta \Gamma_{bsd} b : B'' : s$.

By IH($\Delta \Gamma_{bsd} b : B : s$) there is a $B'' \simeq B$ such that $\Delta \Gamma_{bsd} b : B'' : s$.

But then also $B'' \simeq B'$, so we are done.

**Formation.** The last step in the derivation is

$$\frac{\Delta \Gamma_{bsd} A : s_1 : s_1'}{\Delta \Gamma_{bsd} (\Pi x : A. B) : s_2 : s_2'} (s_1, s_2, s_3) \in R$$

By the IH there are $S_1 \simeq s_1$ and $S_2 \simeq s_2$ such that

$$\Delta, x : A : s_1 \Gamma_{bsd} B : S_2 : s_2' \text{ and } \Delta \Gamma_{bsd} A : S_1 : s_1' \text{.}$$

So by the $\Gamma_{bsd}$-formation rule

$$\frac{\Delta, x : A : s_1 \Gamma_{bsd} B : S_2 : s_2' \text{ and } S_2 \rightarrow s_2}{\Delta \Gamma_{bsd} A : S_1 : s_1'}$$

and $(\Pi x : A. B') \simeq (\Pi x : A. B)$.

**Application.** The last step in the derivation is

$$\frac{\Delta \Gamma_{bsd} (\lambda x : A. B') : s_3 \text{ and } (\Pi x : A. B') \simeq (\Pi x : A. B)}{\Delta \Gamma_{bsd} (\lambda x : A. B') : (\Pi x : A. B') : s_3}$$

By the IH there are $S_1 \simeq s_1$ and $B' \simeq B$ such that

$$\Delta, x : A : s_1 \Gamma_{bsd} B : S_2 : s_2$$

and $(\Pi x : A. B') \simeq (\Pi x : A. B)$.

**Abstraction.** The last step in the derivation is

$$\frac{\Delta \Gamma_{bsd} A : s_1 : s_1'}{\Delta \Gamma_{bsd} (\lambda x : A. B) : (\Pi x : A. B) : S_3 : \text{At}(s_3)} (s_1, s_2, s_3) \in R$$

By the IH there are $S_1 \simeq s_1$ and $B' \simeq B$ such that

$$\Delta, x : A : s_1 \Gamma_{bsd} B : S_2 : s_2' \text{ and } \Delta \Gamma_{bsd} A : S_1 : s_1'$$

So by the $\Gamma_{bsd}$-abstraction rule

$$\frac{\Delta, x : A : s_1 \Gamma_{bsd} B : S_2 : s_2' \text{ and } S_1 \rightarrow s_1}{\Delta \Gamma_{bsd} A : S_1 : s_1'}$$

and $(\Pi x : A. B') \simeq (\Pi x : A. B)$.

**Application.** The last step in the derivation is

$$\frac{\Delta \Gamma_{bsd} (\lambda x : A. B') : s_3 \text{ and } (\Pi x : A. B') = (\Pi x : A. B)}{\Delta \Gamma_{bsd} (\lambda x : A. B') : (\Pi x : A. B') : s_3}$$

By the IH there are $C \simeq (\Pi x : A. B)$ and $A'' \simeq A$ such that

$$\Delta \Gamma_{bsd} C : s_3 \text{ and } \Delta \Gamma_{bsd} a : A'' : s_1.$$

$C \simeq (\Pi x : A. B)$; so there exist terms $A'$ and $B'$ such that $A' \simeq A$, $B' \simeq B$ and $C \rightarrow_{wh} (\Pi x : A'. B')$. Then by the $\Gamma_{bsd}$-application rule

$$\frac{\Delta \Gamma_{bsd} C : s_3 \text{ and } (\Pi x : A'. B') \simeq (\Pi x : A'. B')}{\Delta \Gamma_{bsd} a : A'' : s_1 \text{ and } A'' \simeq A'}$$

and $B'[x := a] \simeq B[x := a]$.  \(\Box\)
In order to prove

$$\Delta \Gamma_{\text{bad}} b : B : s \wedge WF_{\text{bad}} \Delta \Rightarrow \Delta \Gamma_{b} b : B : s$$  \hspace{1cm} (1)

we first prove

$$\Delta \Gamma_{\text{bad}} b : B : s \wedge WF_{b} \Delta \Rightarrow \Delta \Gamma_{b} b : B : s$$  \hspace{1cm} (2)

where $WF_{b} \Delta$ is defined as follows:

\begin{align*}
\text{(empty)} & : WF_{b} \epsilon \\
\text{(weaken)} & : \frac{WF_{b} \Delta \Delta \Gamma_{b} A : s : s'}{WF_{b} \Delta, x : A : s} \quad \text{if } x \text{ is } \Delta\text{-fresh}
\end{align*}

Once we have proved (2), proving $WF_{b} \Delta \Rightarrow WF_{\text{bad}} \Delta$ - and hence (1) - will be simple.

Before we prove (2), some work has to be done.

**Lemma C.2.** For all bijective PTS

$$\Delta \Gamma_{b} b : B : s \Rightarrow WF_{b} \Delta$$

**Proof.** By induction on the derivation of $\Delta \Gamma_{b} b : B : s$. Last step:

**Axiom.** The last step in the derivation is $\epsilon \Gamma_{b} s : s' : A_{T}(s')$, and the empty context is well-formed : $WF_{b} \epsilon$.

**Variable.** The last step in the derivation is

$$\frac{\Delta \Gamma_{b} A : s_{1} : s'_{1}}{\Delta, x : A : s_{1}, \Gamma_{b} x : A : s_{1}}$$

By the IH $WF_{b} \Delta$, so by $WF_{b}$-weakening rule

$$\frac{WF_{b} \Delta \Delta \Gamma_{b} A : s_{1} : s'_{1}}{WF_{b} \Delta, x : A : s_{1}}$$

**Weakening.** The last step in the derivation is

$$\frac{\Delta \Gamma_{b} b : B : s \Delta \Gamma_{b} A : s_{1} : s'_{1}}{\Delta, x : A : s_{1}, \Gamma_{b} b : B : s}$$

By the IH $WF_{b} \Delta$, so by $WF_{b}$-weakening rule

$$\frac{WF_{b} \Delta \Delta \Gamma_{b} A : s_{1} : s'_{1}}{WF_{b} \Delta, x : A : s_{1}}$$

**Conversion, Formation, Abstraction, Application** In these cases the induction step is trivial: none of these rules extend the context, so $WF_{b} \Delta$ follows immediately from the induction hypothesis. \( \square \)

**Lemma C.3.** For bijective PTS : $\Delta \Gamma_{b} b : B : s \Rightarrow \overline{\Delta} \equiv \Delta$, with $\overline{\Delta}$ as defined in lemma B.6.

(Recall that by lemma B.7 $|\Delta| \equiv |\overline{\Delta}|$, with $\overline{\cdot}$ as defined in theorem 3.4 )

**Proof.** In view of lemma C.2 it suffices to prove that for bijective PTS : $WF_{b} \Delta \Rightarrow \overline{\Delta} \equiv \Delta$.

This is proved by induction on $\Delta$. The base case $\Delta \equiv \epsilon$ - is trivial.
Suppose \( \Delta \equiv \Delta', x : A : s \). Then
\[
WF_b \Delta', x : A : s \\
\exists \tau \cdot WF'_b \Delta' \land \Delta' \vdash_f_b A : s' \\
\{ IH \} \\
\exists \tau' \cdot WF'_b \Delta' \land \Delta' \vdash_f_b A : s' \land [\Delta'] \equiv \Delta' \\
\Rightarrow \\
\exists \tau \cdot \Delta' \vdash_f_b A : s' \land [\Delta'] \equiv \Delta' \\
\{ \text{def } \tau' \} \\
[\Delta', x : A : s] \equiv [\Delta', x : A : s \land [\Delta'] \equiv \Delta'] \\
\Rightarrow \\
[\Delta', x : A : s] \equiv [\Delta', x : A : s] \\
\Rightarrow \\
\exists \tau \cdot \Delta' \vdash_f_b A : s \land [\Delta'] \equiv \Delta' \\
\{ \text{def } \tau \} \\
[\Delta', x : A : s] \equiv [\Delta', x : A : s] \\
\Rightarrow \\
[\Delta', x : A : s] \equiv [\Delta', x : A : s] \\
\Rightarrow \\
[\Delta', x : A : s] \equiv [\Delta', x : A : s] \\
\Rightarrow \\
[\Delta', x : A : s] \equiv [\Delta', x : A : s] \\
\Rightarrow 
\]

Using this lemma, \( SR \) can now be siphoned over from \( \vdash \) to \( \vdash_f_b \):

**Lemma C.4.** [Type reduction for \( \vdash_f_b \): TR\(_{\vdash_f_b}\)]

For bijective PTS: if \( \Delta \vdash_f_b b : B : s \) and \( B \beta B' \) then \( \Delta \vdash_f_b b : B' : s \).

**Proof.** Suppose \( B \beta B' \) and \( \Delta \vdash_f_b b : B : s \).

First we prove \( \Delta \vdash_f_b b : B' : s' \) for some \( s' \):

\[
\Delta \vdash_f_b b : B : s \\
\Rightarrow \{ \text{lemma B.1 : } \vdash_f_b b \Rightarrow \} \\
[\Delta] \vdash_f b : B \land (\Delta \vdash_f b : B \lor B \in S) \\
\Rightarrow \{ B \beta B', \text{so } B \notin S \} \\
[\Delta] \vdash_f b : B \land [\Delta] \vdash_f b : B : s \\
\Rightarrow \{ SR_b \text{(lemma A.1)} \} \\
[\Delta] \vdash_f b : B \land [\Delta] \vdash_f b : B : s \\
\Rightarrow \{ \beta \text{-conversion rule} \} \\
[\Delta] \vdash_f b : B' \\
\Rightarrow \{ \text{lemma B.6 : } \beta \Rightarrow \vdash_f_b \} \\
[\Delta] \vdash_f b : B' : s' \text{ for some } s' \\
\]

By lemma C.3, \( \Delta \vdash_f_b b : B : s \Rightarrow [\Delta] \equiv \Delta \).

So it follows from \( \Delta \vdash_f_b b : B : s \) that \( \Delta \vdash_f_b b : B' : s' \) for some \( s' \).

Finally, by UT \(_{\vdash_f_b}\) (lemma B.2) , part (i), it follows that \( s' \equiv s \).

Using TR\(_{\vdash_f_b}\), we can now prove

**Lemma C.5.** For bijective PTS

\[
\Delta \vdash_f b : B : s \land WF_b \Delta \Rightarrow \Delta \vdash_f b : B : s \\
\]

**Proof.** By induction on the derivation of \( \Delta \vdash_f b : B : s \) we prove

\[
\Delta \vdash_f b : B : s \Rightarrow (WF_b \Delta \Rightarrow \Delta \vdash_f b : B : s) \\
\]

Last step:

**Axiom.** The last step in the derivation is \( \Delta \vdash_f b : s' : \mathcal{A}_\tau (s') \), where \( s : s' \in A \).

By the start lemma for \( \vdash_f_b \) (lemma B.3) and lemma C.2: \( WF_b \Delta \Rightarrow \Delta \vdash_f b : s' : \mathcal{A}_\tau (s') \).

**Variable.** The last step in the derivation is \( \Delta, x : A : s, \Delta' \vdash_f b : x : A : s \).

By the start lemma for \( \vdash_f_b \) (lemma B.3) and lemma C.2: \( WF_b \Delta, x : A : s, \Delta' \Rightarrow \Delta, x : A : s, \Delta' \vdash_f b : x : A : s \).

**Formation.** The last step in the derivation is

\[
\Delta, x : A : s_1 \vdash_f b : S_2 : s_2' \\
\Delta \vdash_f b : S_1 : s_1' \\
\Delta \vdash_f (H x : A.B) : s_3 : \mathcal{A}_\tau (s_3) \\
\]

(s_1, s_2, s_3) \in \mathcal{R}

24
To prove: $WF_b \Delta \Rightarrow \Delta F_b (\Pi x : A. B) : s_3 : A_T (s_3)$.

By the IH: $WF_b \Delta, x : A : s_1 \Rightarrow \Delta, x : A : s_1 F_b B : s_2 : s_2' \Rightarrow WF_b \Delta \Rightarrow \Delta F_b A : S_1 : s_1'$

Assume $WF_b \Delta$. Then $\Delta F_b A : S_1 : s_1'$, by $TR_{F_b}$ (lemma C.4) $\Delta F_b A : s_1 : s_1'$ and so $WF_b \Delta, x : A : s_1$.

Then also by the IH: $\Delta, x : A : s_1 F_b B : s_2 : s_2'$.

By $TR_{F_b}$ (lemma C.4): $\Delta, x : A : s_1 F_b B : s_2 : s_2'$, and finally by the $F_b$-formation rule

$$\Delta, x : A : s_1 F_b B : s_2 : s_2' \Rightarrow \Delta F_b (\Pi x : A. B) : s_3 : A_T (s_3)$$

Abstraction. The last step in the derivation is

$$\Delta, x : A : s_1 F_{bad} b : B : s_2 \Rightarrow \Delta F_{bad} A : S_1 : s_1' \Rightarrow S_1 \Rightarrow a \hspace{0.5cm} (s_1, s_2, s_3) \in R$$

To prove: $WF_b \Delta \Rightarrow \Delta F_b (\lambda x : A. b) : (\Pi x : A. B) : s_3$.

By the IH: $WF_b \Delta, x : A : s_1 \Rightarrow \Delta, x : A : s_1 F_b b : B : s_2$

$WF_b \Delta \Rightarrow \Delta F_b A : S_1 : s_1'$.

Assume $WF_b \Delta$. Then $\Delta F_b A : S_1 : s_1'$, by $TR_{F_b}$ (lemma C.4) $\Delta F_b A : s_1 : s_1'$ and so $WF_b \Delta, x : A : s_1$.

Then also by the IH: $\Delta, x : A : s_1 F_b b : B : s_2$.

By $TR_{F_b}$ (lemma C.4): $\Delta F_b A : s_1 : s_1'$, and then by the $F_b$-formation rule

$$\Delta, x : A : s_1 F_b b : B : s_2 \Rightarrow \Delta F_b A : s_1 : s_1'$$

Application. The last step in the derivation is

$$\Delta F_{bad} b : C : s_3 \Rightarrow C \Rightarrow \Delta F_{bad} a : A : s_1 \Rightarrow a \Rightarrow A \Rightarrow a \Rightarrow A' \Rightarrow (s_1, s_2, s_3) \in R$$

To prove: $WF_b \Delta \Rightarrow \Delta F_b b [x := a] : s_2$.

By the IH: $WF_b \Delta \Rightarrow \Delta F_b b : C : s_3$.

$WF_b \Delta \Rightarrow \Delta F_b a : A : s_1$.

Assume $WF_b \Delta$. Then by the IH: $\Delta F_b b : C : s_3$ and $\Delta F_b a : A : s_1$.

Let $A''$ be a common reduct of $A$ and $A'$.

Then by $TR_{F_b}$: $\Delta F_b b : (\Pi x : A''. B) : s_3$ and $\Delta F_b a : A'' : s_1$, so by the $F_b$-application rule

$$\Delta F_b b : (\Pi x : A''. B) : s_3 \Rightarrow \Delta F_b a : A'' : s_1 \Rightarrow \Delta F_b b [x := a] : s_2$$

Finally, we still have to prove $\Delta F_b b : B : s \Rightarrow WF_{bad} \Delta$.

**Lemma C.6.** For all bijective $PTS : \Delta F_b b : B : s \Rightarrow WF_{bad} \Delta$.

**Proof.** By lemma C.2 it suffices to prove $WF_{bad} \Delta \Rightarrow WF_{bad} \Delta$. This is proved by induction on the structure of $\Delta$. The case $\Delta \equiv c$ is trivial. Suppose $\Delta \equiv \Delta', x : A : s$. Then

$WF_{bad} \Delta', x : A : s$

$\iff \{ definition WF_b \}$

$\exists_x WF_{bad} \Delta' \land \Delta' F_b A : s : s'$

$\iff \{IH\}$

$\exists_x WF_{bad} \Delta' \land \Delta' F_b A : s : s'$

$\iff \{ lemma C.1 : F_b \Rightarrow WF_{bad} \}$

$\exists S, s, WF_{bad} \Delta' \land \Delta' F_{bad} A : S : s' \land S \Rightarrow s$

$\iff \{ definition WF_{bad} \}$

$WF_{bad} \Delta', x : A : s$

$\square$
Theorem 3.4: \( \vdash \iff \vdash_t \)

We now prove theorem 3.4: for all functional PTS

\[
\Gamma \vdash b : B \Rightarrow (\exists s \in S_\Gamma. \ \Gamma_t \vdash b : B) \\
\Delta \vdash b : B : s \Rightarrow [\Delta] \vdash b : B \land ([\Delta] \vdash B : s \lor (B : s) \in A_t \setminus A)
\]

This is proved in the same way theorem 3.7 was proved in appendix B. Only when the application rule is involved is there any difference. This main difference is in the first half: in the proof of lemma D.7 a substitution lemma for \( \vdash_t \) (lemma D.6) is required to deal with the application rule.

Lemma D.1. For all functional PTS

\[
\Delta \vdash b : B : s \Rightarrow [\Delta] \vdash b : B \land ([\Delta] \vdash B : s \lor (B : s) \in A_t \setminus A)
\]

Proof. By induction on the derivation of \( \Delta \vdash b : B : s \). Only if the last step is the application rule is there any difference with the proof of lemma B.1.

Application. The last step in the derivation is

\[
\Delta \vdash b : B : s \\
\Delta \vdash a : A : s_1 \\
\Delta \vdash B[x := a] : s_2 : s'_2 \\
\Delta \vdash ba : B[x := a] : s_2
\]

To prove:

(i) \( [\Delta] \vdash ba : B[x := a] \)

(ii) \( [\Delta] \vdash B[x := a] : s_2 \lor (B[x := a] : s_2) \in A_t \setminus A \)

By the IH \( [\Delta] \vdash B[x := a] : s_2 \), so (ii) holds. By the IH \( [\Delta] \vdash b : (\Pi x : A. B) \) and \( [\Delta] \vdash a : A \), so the \( \vdash_t \) application rule yields (i):

\[
[\Delta] \vdash b : (\Pi x : A. B) \quad [\Delta] \vdash a : A \\
[\Delta] \vdash ba : B[x := a]
\]

\[\square\]

Lemma D.2. (uniqueness of types for \( \vdash_t : U T_{\mathcal{F}_t} \))

(i) If \( \Delta \vdash b : B : s \) and \( \Delta \vdash b : B' : s' \) then \( s \simeq s' \).

(ii) If \( \Delta \vdash b : B : s \) and \( \Delta \vdash B : s' \) then \( s \simeq s' \).

Proof. Exactly as lemma B.2.

\[\square\]

Lemma D.3. (start lemma for \( \vdash_t \))

If \( \Delta \vdash b : B : s \) and \( (s : s') \in A_t \), then \( \Delta \vdash s : A_t(s') \).

If \( \Delta, x : A : s, \Delta' \vdash b : B : s \) then \( \Delta, x : A : s, \Delta' \vdash x : A : s \).

Proof. Exactly as lemma B.3.

\[\square\]

Lemma D.4. (thinning lemma for \( \vdash_t \))

Suppose \( \Delta' \vdash b : B : s \), \( \Delta' \subseteq \Delta \) and \( \Delta \vdash a : s' \).

Then \( \Delta \vdash b : B : s \).

Proof. Exactly as lemma B.4.

\[\square\]

Lemma D.5. (\( \Pi \)-generation lemma for \( \vdash_t \))

Let \( \Delta \vdash (\Pi x : A. B) : s_3 : s'_3 \). Then there are \( s_1, s_2, s'_2 \) such that \( (s_1, s_2, s_3) \in R_t \), \( \Delta \vdash A : s_1 : s'_1 \) and \( \Delta, x : A : s_1, \Delta \vdash B : s_2 : s'_2 \).

Proof. Exactly as lemma B.5.

\[\square\]
Lemma D.6. [substitution lemma for $\Gamma_f$]
Suppose $\Delta, x : C : s, \Delta' f b : B : s'$ and $\Delta f c : C : s$.

Proof. By induction on the derivation of $\Delta, x : C : s, \Delta' f b : B : s'$.

Lemma D.7. For functional PTS

$$\Gamma \vdash b : B \Rightarrow (\exists s \in S_T. \overline{\Gamma} f b : B : s)$$

where $\overline{\Gamma}$ is defined by

$$\frac{\overline{\Gamma}, x : A \Rightarrow \overline{\Gamma}, x : A : s \quad \text{if } \overline{\Gamma} f A : s : s'}{\overline{\Gamma}}$$

N.B. In lemma B.6 $\overline{\Gamma}$ is defined differently, viz. in terms of $f b$ instead of $f t$.

Proof. By induction on the derivation of $\Gamma \vdash b : B$. Only if the last step is the application rule
there is any difference with the proof of lemma B.6.

Application. The last step in the derivation is

$$\frac{\Gamma \vdash (\Pi x : A. B) \quad \Gamma \vdash a : A}{\Gamma \vdash \Pi f a : B[x := a]}$$

To prove: $(\exists s \in S_T. \overline{\Gamma} f \Pi a : B[x := a] : s)$.

By the IH there are $s_2$ and $s_1$ such that

$$\overline{\Gamma} f \Pi a : A : s_3$$

$$\overline{\Gamma} f a : A : s_1$$

By the $\Pi$-generation lemma for $f$ it follows from (1) that there are $t_1, t'_1, s_2$ and $s'_2$ with

$$(t_1, s_2, s_3) \in \mathcal{R}$$

such that

$$\overline{\Gamma} f A : t_1 : t'_1$$

$$\overline{\Gamma}, x : A : t_1 f B : s_2 : s'_2$$

By $UT_{\Gamma f}$, $t_1 \equiv s_1$, so by the substitution lemma for $f$ it follows from (2) and (4) that

$$\overline{\Gamma} f B[x := a] : s_2 : s'_2$$

Now by the $f$ application rule

$$\overline{\Gamma} f \Pi a : (\Pi x : A. B) : s_3$$

$$\overline{\Gamma} f a : A : s_1$$

$$\overline{\Gamma} f B[x := a] : s_2 : s'_2$$

$$\overline{\Gamma} f ba : B[x := a] : s_2$$

Lemma D.8. The two ways to extend $\Gamma$-contexts to $\Gamma_f$-contexts used in theorem 3.4 and the previous lemma are the same, i.e. $\overline{\Gamma} \equiv \overline{\Gamma}$.

Proof. Exactly as lemma B.7.
