DIRECT SOLUTION OF
CERTAIN SPARSE LINEAR SYSTEMS

by
R.M.M. Mattheij
This paper deals with sparse linear systems which arise among other cases when solving boundary value problems. These matrices have a bidiagonal blockstructure plus potentially some nontrivial blocks as last column and or row. The analogy with BVP is employed to relate it to theory of discretized ODE. The underlying structure of the solution space, following from well-conditioning, then induces a direct solution method (based on decoupling). The strategy is shown to work for fairly general cases.
1. Introduction.

A number of problems in numerical analysis leads to the formulation of a linear system where the (sparse) matrix typically has a structure as in fig. 1.1.

![Matrix Structure](image)

Fig. 1.1

Here × stands for a matrix which is \( n \times n \) in the left upper part (as indicated by the dotted line), has \( m \) rows in the last block row and has \( m \) columns in the last block column.

In principle we need not require that the square blocks be nonsingular, but for our analysis it is helpful to have some simplifying assumptions. For a paper which deals with more general cases we may e.g. refer to [7]. Matrices as in (1.1) arise, for instance, in system theory and in numerical solutions of boundary value problem (BVP) for differential equations. For a general nonlinear BVP, one usually solves via linearization, i.e. by a sequence of linear problems in which the Jacobian of some sort gives rise to a matrix as in fig. 1.1. As can be found in [1], most numerical methods actually lead (possibly after some form of condensation) to a multiple shooting system of which the left upper part in fig. 1.1 is reminiscent. Actually, in this paper we like to employ this fact by relating such matrices to special BVP. This will enable us to use a number of important results of the theory of those problems for establishing a stable direct method for solving linear systems with such a matrix.

To this end we first consider general linear ODE of the form

\[
\frac{dx}{dt} = L(t)x + C(t)\lambda + f(t), \quad \alpha \leq t \leq \beta
\]

where
After discretisation of (1.1) by say a difference method we obtain, possibly after condensation (e.g. a local "shooting" approach), a difference equation for the solution at certain nodes, \( t_1, \ldots, t_N \) say. If we neglect discretisation errors, we can write

\[
(1.2a) \quad x_i = x(t_i) \\
(1.2b) \quad X^T = (x_1^T, x_N^T, \lambda^T),
\]

for the unknown solution values. In a multiple shooting framework, we typically get a difference equation

\[
(1.3a) \quad A_i x_i + B_i x_{i+1} + C_i \lambda = f_i
\]

By writing

\[
(1.3b) \quad (F^T)^T = (f_1^T, \ldots, f_{N-1}^T),
\]

and

\[
A^1 = \begin{bmatrix}
A_1 & B_1 & C_1 \\
A_2 & B_2 & \vdots \\
\vdots & \vdots & \vdots \\
A_{N-1} & B_{N-1} & C_{N-1}
\end{bmatrix},
\]

the discretised ODE results in the following set of equations

\[
(1.5) \quad A^1 X = F^1
\]

(To fix thoughts, often \( B_i = -I \) for multiple shooting and thus \( A_i \) represents the incremental matrix, going from \( t_i \) to \( t_{i+1} \))

As for the boundary conditions (BC), we let them be of the form

\[
(1.6a) \quad \sum_{i=1}^{N} M_i x(t_i) + E_N \lambda = b \\
(1.6b) \quad P_1 x(t_1) + P_N x(t_N) + E_{N+1} \lambda = c
\]

where

\[ M_i \in \mathbb{R}^{n \times n} \]
(More general BC are also possible, but (1.6) is sufficiently general, given \( t_1, \ldots, t_N \).
Clearly (1.6) gives rise to \( n + m \) additional equations

\[
A^2 X = F^2,
\]

where

\[
(1.8a) \quad A^2 = \begin{bmatrix}
M_1 & M_2 & \cdots & M_N & E_N \\
P_1 & 0 & \cdots & P_N & E_{N+1}
\end{bmatrix}
\]

\[
(1.8b) \quad F^2 = \begin{bmatrix} b \\ c \end{bmatrix}
\]

There are several special cases which deserve a special consideration:

**I Two Point BVP:**

\[
C_1, \ldots, C_N \\
P_1, P_N \\
E_N, E_{N+1}
\]

are absent

\[
M_2 = \cdots = M_{N-1} = 0
\]

**II Multipoint BVP:**

\[
C_1, \ldots, C_N \\
P_1, P_N \\
E_N, E_{N+1}
\]

are absent

**III Two point parameter BVP:**

\[
M_2 = \cdots = M_{N-1} = 0
\]

In section 2 we discuss the properties of the underlying subspaces in each of the cases I, II, III. The more general structure of the matrix \( A \), defined by
will then be dealt with in section 3. The basic algorithm on which our method is built is given in section 4. Finally, we show how this is used to solve the general problem.

\[ A X = F, \]

where

\[ F = \begin{bmatrix} F_1 \\ F_2 \end{bmatrix} \]
2. On dichotomy and (skew) polychotomy

The various kinds of BVP have solution spaces with a potentially different character. This is a very important aspect as our direct methods for solving (1.10) will be based on finding a stable way for actually determining this solution space.

Let us consider the homogeneous part of (1.3a)

\[ A_i \, x_i + B_i \, x_{i+1} = 0, \]  

and let us denote by \( \{ \Phi_i \}_{i=1}^N \) a fundamental system of (2.1). In order to derive some properties for \( \{ \Phi_i \} \), we shall assume throughout this paper that \( \| A^{-1} \| \) is not large:

**Assumption 2.2** Let \( \kappa \) be a not large positive constant and let \( \| A^{-1} \| \leq \kappa. \)

For the simplest case, with two point BC, a simple splitting of the solution space can be indicated in which the Green’s function (buried in \( A^{-1} \)) is used, cf \([2,3]\). We summarize the discrete analogue of \([3]\) in the following

**Property 2.3** (case I, Two Point BVP).
If \( C_1, \ldots, C_N, P_1, P_N, E_N, E_{N+1} \) are absent and \( M_2 = \cdots = M_{N-1} = 0 \), then it is not restrictive to assume that \( \{ \Phi_i \}_{i=1}^N \) is dichotomic, i.e. there exists an orthogonal projection \( P \) with

\[ \| \Phi_i \, P \, \Phi_{i+1} \| \leq \kappa, \quad i > j \]

\[ \| \Phi_i \, (I-P) \, \Phi_{i+1} \| \leq \kappa, \quad i \leq j \]

From this property it follows e.g. for a solution \( \{ \phi_i \} \), with \( \phi_i = \Phi_i \, c \), \( c \in \mathbb{R}^n \),

\[ \frac{\| \phi_i \|}{\| \phi_{i+1} \|} = \frac{\| \Phi_i \, P \, c \|}{\| \Phi_{i+1} \, P \, c \|} \leq \max_{y \neq 0} \frac{\| \Phi_i \, P \, \Phi_{i+1} \, y \|}{\| y \|} \leq \kappa, \quad i > j \]

In other words, \( \{ \phi_i \} \) is "non-increasing". Similarly \( \{ \psi_i \} \), with \( \psi_i = \Phi_i \, (I-P) \, d \), \( d \in \mathbb{R}^n \) is a "non-decreasing" solution. Moreover, dichotomy implies that the two thus indicated solution subspaces cannot be directionally close (cf \([2]\)).

For multipoint BC there exists the following generalisation (see \([4]\)).

**Property 2.4** (case II, Multipoint BVP).
If \( C_1, \ldots, C_N, P_1, P_N, E_N, E_{N+1} \) are absent, then it is not restrictive to assume that \( \{ \Phi_i \}_{i=1}^N \) in polychotomic, i.e. there exist orthogonal projections \( P_1, \ldots, P_l, l \leq n \) with
\[
\sum_{j=1}^{l} P_j = I, \quad \sum_{j=1}^{l} \text{rank}(P_j) = n
\]

and corresponding indices \(1 = i_1, \ldots, i_{l} = N\) such that

\[
\| \Phi_i \left( \sum_{j=1}^{k} P_j \right) \Phi_{j+1}^{-1} \| \leq \kappa, \quad i_k \leq j < i_{k+1}, \quad i > j
\]

\[
\| \Phi_i \left( \sum_{j=k+1}^{n} P_j \right) \Phi_{j+1}^{-1} \| \leq \kappa, \quad i_k \leq j < i_{k+1}, \quad i \leq j
\]

Hence for multipoint BVP we see that on each interval \([t_i, t_{i+1}]\) the solution space is dichotomic, but that the dimension of the "non-increasing" mode subspace may increase from \([t_i, t_{i+1}]\) to \([t_{i+1}, t_{i+2}]\).

As before the subspaces do not make small angles. So a typical solution may be either "non-decreasing" or "non-increasing" everywhere, or may be "non-decreasing" till some point \(t_\alpha\), after which it becomes "non-increasing". In fig. 2.1 we have sketched these three possibilities.

![Fig. 2.1](image)

Finally, we have

**Property 2.5 (case III, Two Point BVP with parameters)**

If \(M_2 = \cdots = M_N = 0\), then it is not restrictive to assume that \(\{ \Phi_i \}_{i=1}^{N}\) is
skew polychotomic, i.e. there exist orthogonal projections $P_1, \cdots, P_l$, $l \leq n$, with
\[ \sum_{j=1}^{l} P_j = I, \quad \sum_{j=1}^{l} \text{rank}(P_j) = n \] and corresponding indices $1 = i, \cdots, i_l = N$ such that
\[ \| \Phi_{j+1} \left( \sum_{j=1}^{k} P_j \right) \Phi_{i}^{-1} \| \leq \kappa, \quad i_k \leq j < i_{k+1}, \quad i > j \]
\[ \| \Phi_{j+1} \left( \sum_{j=k+1}^{n} P_j \right) \Phi_{i}^{-1} \| \leq \kappa, \quad i_k \leq j \leq i_{k+1}, \quad i \leq j \]

Hence for parameter BVP we see that again the solution space is dichotomic interval wise, but that the dimension of the non-decreasing mode subspace may increase from $[t_i, t_{i+1}]$ to $[t_{i+1}, t_{i+2}]$. So a typical solution may either be "non-increasing" or "non-decreasing" or be "non-increasing" till some point $t_i$ after which it becomes "non-decreasing". In fig 2.1 we have sketched these three possibilities.

Fig. 2.2

It should be noted that case II is related to case III in that after some manipulation a matrix arising in one case can be viewed as the transpose of the other. To see these, consider e.g. case II.

Here we have
After writing the first block row of $A^T$ last we obtain

$$\tilde{A}^T := \begin{bmatrix} B_1^T & A_2^T & \cdots & A_{N-1}^T \\ B_2^T & \cdots & \cdots & B_{N-1}^T \\ \cdots & \cdots & \cdots & \cdots \\ B_N^T & M_N^T & E_N^T & E_{N+1}^T \\ C_1^T & C_2^T & \cdots & C_{N-1}^T \\ A_1^T & \cdots & \cdots & P_1^T \\ \varnothing & \cdots & \varnothing & M_1^T \\ * & \cdots & * & E_{N+1}^T \end{bmatrix}$$

Next we realize that the last two block columns (with n and m columns respectively) constitute a full column rank ($= n+m$) system. Hence it is not restrictive to assume $P_N = 0$. Since now $P_f$ must have rank $m$ we may permute the last $m+n$ rows of $\tilde{A}^T$ in order to have a non-singular block at the place of $E_{N+1}^T$. For simplicity let us assume that $E_{N+1}^T$ is already non-singular; then we can use this to eliminate $C_1^T$, $C_2^T$, $\cdots$, $C_{N-1}^T$, $E_N^T$, thereby producing potential fill-in in the last block row. Summarizing, there exists a well-conditioned equivalence transformation for $\tilde{A}^T$ giving a matrix $\tilde{A}^T$ say with

$$\tilde{A}^T := \begin{bmatrix} B_1^T & A_2^T & \cdots & A_{N-1}^T \\ B_2^T & \cdots & \cdots & B_{N-1}^T \\ \cdots & \cdots & \cdots & \cdots \\ B_N^T & M_N^T & \varnothing \\ \varnothing & \cdots & \varnothing & \varnothing \\ * & \cdots & * & E_{N+1}^T \end{bmatrix}$$

obviously, we can eliminate the last block variable, which effectively means deleting the N-th block row and (N + 1)-st block column (both of rank m). Clearly the resulting matrix is of type II.
3. The structure of the solution space, general case.

Now consider the general case where \( A \) has the form as in fig. 1.1, i.e. we have a multipoint parameter problem. The situation here is more complicated. Rather than analyzing it in detail, we shall consider an example to illustrate this. Since the solution methods we shall propose later only work for any of the cases I, II or III, mentioned before, this will be sufficient to motivate our approach for the more general case.

Consider the following matrix \( A \)

\[
A = \begin{bmatrix}
\varepsilon & 0 & -1 & 0 & 0 & 0 \\
0 & 1 & 0 & -\varepsilon & 0 & 0 \\
0 & 0 & 1 & 0 & -\varepsilon & 0 \\
0 & 0 & 0 & \varepsilon & 0 & -1 \\
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 1
\end{bmatrix}, \quad \varepsilon > 0
\]  

(3.1)

From (3.1) we see

\[
\begin{align*}
\begin{bmatrix}
\varepsilon & 0 \\
0 & 1
\end{bmatrix} \Phi_1 &= \begin{bmatrix} 1 & 0 \\
0 & \varepsilon
\end{bmatrix} \Phi_2 \\
\begin{bmatrix} 1 & 0 \\
0 & \varepsilon
\end{bmatrix} \Phi_2 &= \begin{bmatrix} \varepsilon & 0 \\
0 & 1
\end{bmatrix} \Phi_3
\end{align*}
\]

(3.2a) \hspace{1cm} (3.2b)

Writing \( \Phi_i = \begin{bmatrix} \phi_i^1 \mid \phi_i^2 \end{bmatrix} \), we may identify \( \{ \phi_i^1 \}, \{ \phi_i^2 \} \) as follows

\[
\begin{align*}
\phi_1^1 &= \begin{bmatrix} 1 \\
0
\end{bmatrix}, \quad \phi_2^1 = \begin{bmatrix} \varepsilon \\
0
\end{bmatrix}, \quad \phi_3^1 = \begin{bmatrix} 1 \\
0
\end{bmatrix} \\
\phi_1^2 &= \begin{bmatrix} 0 \\
\varepsilon
\end{bmatrix}, \quad (\phi_2^2) = \begin{bmatrix} 0 \\
1
\end{bmatrix}, \quad \phi_3^2 = \begin{bmatrix} 0 \\
\varepsilon
\end{bmatrix}
\end{align*}
\]

(3.3a) \hspace{1cm} (3.3b)
In other words, since these basis modes are clearly directionally well separated, we may conclude that there is no polychotomic, no skew polychotomic fundamental solution. Yet, the matrix $A$ is well conditioned. For, if we premultiply $A$ by

\[
L = \begin{bmatrix}
1 & 0 & 1 \\
0 & 1 & 0 \\
1 & 0 & 1
\end{bmatrix},
\]

(3.4)

we see that $L A$ is a permutation matrix perturbed by a matrix of norm $= \varepsilon$. Hence we conclude that $\|A^{-1}\| \leq 2(1+\varepsilon) =: \kappa$.

However, we may reduce, at the expense of increasing the dimension of the recursion, the general problem to a multipoint BVP, giving the possibility to identify the resulting subspace as polychotomic. We proceed as follows:

Write

\[
Z_i = \begin{bmatrix} x_i \\ \lambda \end{bmatrix}
\]

(3.5)

For the sake of simplicity we take $B_i = -I$ for $i = 1, \cdots, N-1$ from now on. Then we
obtain the augmented system.

\[ (3.6) \quad z_{i+1} = \begin{bmatrix} A_i & C_i \\ 0 & I \end{bmatrix} z_i \quad (+ \text{ inh. term}) \]

and from (1.6) the multipoint BC

\[ (3.7) \quad \sum_{i=1}^{N} M_i z_i = b = \begin{bmatrix} b \\ c \end{bmatrix} \]

where

\[ (3.8a) \quad M_1 = \begin{bmatrix} M_1 & \varnothing \\ P_1 & \varnothing \end{bmatrix} \]

\[ (3.8b) \quad M_i = \begin{bmatrix} M_i & \varnothing \\ \varnothing & \varnothing \end{bmatrix}, \quad z \leq i \leq N-1 \]

\[ (3.8c) \quad M_N = \begin{bmatrix} M_N & E_N \\ P_N & E_{N+1} \end{bmatrix} \]

From (3.6) and (3.7) we find the an augmented system

\[ (3.9) \quad \tilde{A} = \begin{bmatrix} A_1 & C_1 & -I & \varnothing \\ \varnothing & I & \varnothing & -I \\ & & \ddots & \ddots \\ & & & A_{N-1} & C_{N-1} & -I & 0 \\ & & & \varnothing & I & \varnothing & -I \\ & & & & M_1 & \ddots & \ddots & M_{N-1} & M_N \end{bmatrix} \]

By obvious permutations \( P_1, P_2 \) we find

\[ (3.10) \quad \tilde{A} := P_1 \tilde{A} P_2 = \begin{bmatrix} A_1 & -I \\ A_2 & -I \\ \ddots & \ddots \\ A_{N-1} & -I \\ \varnothing & \varnothing & \varnothing & M_1 & M_2 & \ddots & M_N \\ P_1 & \varnothing & \ddots & \varnothing & P_N \\ & \varnothing & \ddots & \varnothing & \varnothing & \ddots & E_N \end{bmatrix} \]

Finally, after postmultiplication by the matrix \( B \), defined as
(B is partitioned in the same way as \( \hat{A} \)), we obtain

\[
B := \begin{pmatrix}
I & & & & \\
& I & & & \\
& & \emptyset & & \\
& & & I & \\
& & \emptyset & & I
\end{pmatrix}
\]

\[(3.11)\]

From (3.12) we then immediately find

**Property 3.13** \[ \|A^{-1}\|_\infty \leq \kappa_\infty (1 + N(1 + \max_i \|C_i\|_\infty)) \]

We therefore conclude that \( \hat{A} \) has a similar conditioning as \( A \). Now we can use Property 2.4 and deduce that the augmented BVP (3.6), (3.7) has a polychotomic fundamental solution.

Instead of forming (3.5) we may alternatively define

\[
(3.14) \quad y_i := \begin{bmatrix}
x_i \\
\sum_{j=1}^{i-1} M_j x_j
\end{bmatrix}
\]

Then we obtain the following augmented system

\[
(3.15) \quad y_{i+1} = \begin{bmatrix}
A_i & \emptyset \\
M_i & I
\end{bmatrix} y_i + 1 \begin{bmatrix}
C_i \\
0
\end{bmatrix} \lambda,
\]

for which we have the two point BC
By similar arguments as used above for the reduction to a multipoint case, it is not hard to show now that (3.15), (3.16) constitutes a well conditioned system if A is. Hence we find from Property 2.5 that the fundamental solution of (3.15) may be thought skew polychotomic.

Whether we prefer the augmented system (3.6) or (3.15) depends mainly on the sizes of the blocks. Clearly (3.6) involves order 2n matrices. For N not too small the multipoint system therefore seems to be preferable if \( m \leq n \).
4. Solution methods

From the preceding sections we deduce that we may restrict ourselves to constructing direct solvers for cases I, II and III. As has been shown e.g. in [6], a crucial concept in solving BVP numerically is decoupling. We merely repeat some important aspects here.

Assume we have a dichotomy (on intervals \([t_j, t_{j+1}]\) this is always the case)

The method consists of the following major steps

(i) Transform the recursion (2.1) such that the matrices are in upper triangular form. This is done recursively and an appropriate initialization should take place.

(ii) Compute the various modes of the two ("dichotomic") subspaces as well as an appropriate particular solution by employing forward and backward recursion of the decoupled parts.

(iii) Use superposition to single out the required solution from the BC.

We demonstrate this for a general inhomogeneous recursion (cf [8]). Let

\[ A_i x_i + B_i x_{i+1} = f_i \]

Choose a suitable orthogonal matrix \(Q_1\); by "suitable" we mean such that the first, say \(k\), columns of \(Q_1\) (if \(\text{rank}(P) = k\)) span a subspace of initial values of modes that do not belong to \(\{\Phi_i P\}_{i=1}^{N}\) (cf Property 2.3), i.e. no "non decreasing" ones. Then compute

\[
\begin{align*}
(4.2a) & \quad A_1 Q_1 = R_1 U_1, \\
(4.2b) & \quad R_1^{-1} B_1 = V_1 Q_2^{-1},
\end{align*}
\]

where \(R_1\) is orthogonal and \(U_1\) upper triangular.

Next compute

\[
(4.2b) & \quad R^{-1} B_1 = V_1 Q_2^{-1},
\]

where \(V_1\) is upper triangular and \(Q_2\) orthogonal.

The general step reads:

Perform a "QU-decomposition":

\[
(4.3a) & \quad A_i Q_i = R_i U_i
\]

and a "UQ-decomposition"

\[
(4.3b) & \quad R_i^{-1} B_i = V_i Q_{i+1}^{-1}
\]

If we set

\[
(4.4a) & \quad \tilde{M}_1 := M_1 Q_1 \\
(4.4b) & \quad \tilde{M}_N := M_N Q_N,
\]

and define
Then the transformation (4.2) - (4.4) result in the following system

\[
\begin{bmatrix}
R_1^{-1} \\
R_2^{-1} \\
\vdots \\
R_N^{-1} \\
I
\end{bmatrix}
\]

\[
R :=
\begin{bmatrix}
Q_1 \\
Q_2 \\
\vdots \\
Q_N
\end{bmatrix}
\]

By introducing new variables

\[
xi := Q_i^{-1} x_i, \quad j_i := R_i f_i,
\]

we see that (4.7) represents a \textit{decoupled} recursion for \{\tilde{x}_i\},

\[
U_i \tilde{x}_i + V_i \tilde{x}_{i+1} = \tilde{j}_i
\]

Because of our well conditioning, we have dichotomy, also for the transformed problem: Assume rank(P) = k (see Property 2.3). Then partition matrices and vectors like:

\[
U_i = \begin{bmatrix} U_{i11} & U_{i12} \\ \varnothing & U_{i22} \end{bmatrix}, \quad U_i^{11} \in \mathbb{R}^{k \times k}
\]

\[
\tilde{x}_i = \begin{bmatrix} \tilde{x}_i^1 \\ \tilde{x}_i^2 \end{bmatrix}
\]

We now have

\textbf{Property 4.12} The partitioning, induced by the dichotomy, implies a decoupling of non increasing and non decreasing modes, which can therefore be computed separately and in a stable way.
So, from (4.9), (4.10) and (4.11) we find

\[(4.13a) \quad U^{22}_{i} \bar{x}^{2}_{i} + V^{22}_{i} \bar{x}^{2}_{i+1} = \bar{f}^{2}_{i}\]

In Property 4.12 it is meant that (4.13a) is a stable recursion in forward direction, so for \(i = 1, \ldots, N-1\). We also obtain

\[(4.13b) \quad U^{11}_{i} \bar{x}^{1}_{i} + V^{11}_{i} \bar{x}^{1}_{i+1} = f_{i} - U^{12}_{i} \bar{x}^{2}_{i} - V^{12}_{i} \bar{x}^{2}_{i+1}\]

Considering the right hand side in (4.13b) as a source term (known if (4.13a) has been carried out earlier), it is implied that (4.13b) is a stable recursion in backward direction, so for \(i = N-1, \ldots, 1\).

These decoupled recursions are used now to complete both a fundamental solution and some particular solution. First the computation of a fundamental solution:

Choose

\[(4.14a) \quad \bar{\Phi}^{2}_{i} = \{ \varnothing | I \} (I = I_{k})\]

and compute \(\bar{\Phi}^{2}_{1}, \ldots, \bar{\Phi}^{2}_{N}\) via the homogeneous part of (4.13a). Then use this to compute \(\bar{\Phi}^{1}_{N}, \ldots, \bar{\Phi}^{1}_{1}\) from (4.13b), satisfying the "terminal condition"

\[(4.14b) \quad \bar{\Phi}^{1}_{N} = \{ I | \varnothing \}, (I = I_{N-k})\]

Next, compute a particular solution:

Choose

\[(4.15a) \quad \bar{p}^{2}_{1} = 0,\]

and compute \(\bar{p}^{2}_{2}, \ldots, \bar{p}^{2}_{N}\) via (4.13a). Then choose

\[(4.15b) \quad \bar{p}^{1}_{N} = 0,\]

and compute \(\bar{p}^{1}_{N-1}, \ldots, \bar{p}^{1}_{1}\), via (4.13b).

Linearity implies that there exists a vector \(c\) such that

\[(4.16) \quad \bar{x}_{i} = \bar{\Phi}_{i} c + \bar{p}_{i}, i = 1, \ldots, N,\]

which can be found from the BC (cf 4.4)

\[(4.17) \quad \bar{M}_{1} \bar{x}_{1} + \bar{M}_{N} \bar{x}_{N} = b,\]

Hence we have to solve the \(th\) order linear system

\[(4.18) \quad [ \bar{M}_{1} \bar{\Phi}_{1} + \bar{M}_{N} \bar{\Phi}_{N} ] c = b - \bar{M}_{1} \bar{p}_{1} - \bar{M}_{N} \bar{p}_{N}.\]

Once we have found \(\{\bar{x}_{i}\}\) via (4.16) our desired solution \(\{x_{i}\}\) follows from (cf 4.8)

\[(4.19) \quad x_{i} := Q_{i} \bar{x}_{i}\]

For multipoint problems this uniform partitioning may not be stable anymore, as the dichotomy
may change from interval to interval. However the partitioning of the blocks at the various intervals can be done in a monotonic way (cf Property 2.4). This was outlined more precisely in [5]. We shall not go into detail here but remark that the essential adaptation is rather obvious: One should prescribe that part of the identity matrix as an "initial-middle-terminal" value for \( \{ \Phi_i \} \) where a corresponding "multipoint" condition gives rise to this. This can be done in practice by monitoring the change in dichotomy pattern (as actually shown by incremental values found from comparing \( U_i \), \( V_i \)). At a point where some unit vectors serve as "starting values" for certain components of \( \Phi_i \) we also choose the corresponding coordinates of \( \tilde{\Phi}_i \) to be zero.

We illustrate this by the following three point BC (cf (1.6a))

\[
M_1 = \begin{bmatrix}
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 1
\end{bmatrix},
M_2 = \begin{bmatrix}
0 & 1 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{bmatrix},
M_3 = \begin{bmatrix}
1 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{bmatrix}
\]

Denoting by superscripts the index of the rows and coordinates in \( \{ \Phi_i \} \) and \( \{ \tilde{\Phi}_i \} \) respectively, we choose

\[
(4.21a) \quad \Phi^3_1 = [0 0 1]
\]

Then \( \Phi^3_2 \) is found from the (decoupled) recursion By choosing

\[
(4.21b) \quad \Phi^3_2 = [0 1 0]
\]

we can use \([010]^{00*}\) as an initial value on the last interval. For backward recursion we finally set

\[
(4.21c) \quad \Phi^3_3 = [1 0 0],
\]

and compute \( \Phi^3_2 \); at this point we augment this part of the fundamental matrix with \( \Phi^3_2 \), so use \([010]^{00*}\) as "starting value" for backward recursion on the first interval. Schematically, this yields a fundamental solution \( \{ \Phi_i \} \) as in fig. 4.1

\[
\Phi_1 = \begin{bmatrix}
\Delta & \Delta & \Delta \\
0 & \Delta & \Delta \\
0 & 0 & 1
\end{bmatrix},
\Phi_2 = \begin{bmatrix}
\Delta & \Delta & \Delta \\
0 & 1 & 0 \\
0 & 0 & *
\end{bmatrix},
\Phi_3 = \begin{bmatrix}
1 & 0 & 0 \\
0 & * & * \\
0 & 0 & *
\end{bmatrix}
\]

\(* = \text{computed forward}
\Delta = \text{computed backward}\n
fig. 4.1

In a similar way we find \( \{ \tilde{\Phi}_i \} \) viz. using the BC
(4.22) \[ \tilde{p}_1^3 = 0 \, , \, \tilde{p}_2^2 = 0 \, , \, \tilde{p}_3^1 = 0 \]

Superposition and backtransformation go essentially the same as for the two point case. With an adaption of argument one can also use such a technique in the skew polychotomic case, which we shall not dwell upon here. (more details are given in [10])
5. Conclusions

Given a system $A$ as in fig. 5.1,

\[
\begin{bmatrix}
\times & \times & \times \\
\times & \times & \times \\
\times & \times & \times \\
\times & \times & \times \\
\times & \times & \times \\
\times & \times & \times \\
\end{bmatrix}
\]

fig. 5.1

We decide from the last block row/columns, whether we effectively have either of the following cases:

I  two-point BVP
II  multipoint BVP
III two point BVP with parameters
IV  multipoint BVP with parameters

In case I we use the "standard" decoupling technique, outlined in section 4. In cases II and III we use an adapted decoupling technique (in which a possible change of the dichotomy partitioning is accounted for).

Finally, in case IV we rewrite the BVP as either a case II or a case III BVP as shown in section 2, after which we can use the method for case II or III respectively. An augmented multipoint system is to be preferred over an augmented parameter system as long as $m \leq n$.
