ACKNOWLEDGEMENTS

I would like to thank the supervision committee for all the important remarks made during the making of this project.
Special thanks to Martien Ceelen for his ideas and improvements of all the little details corresponding to the experimental setup. In general, thanks to all the people in the laboratory who contributed in this research.
Finally, I would like to thank Dr. Alessandro DiBucchianico for his help and contribution on the statistical analysis.
1. INTRODUCTION

This research deals with the determination of the embedding strength of two kinds of plybamboo: bamboo mat board (MB) from India and bamboo strip board (SB) from China.

The results presented in this report would be of important use for the calculation of the capacity of lateral-loaded nailed connections between plybamboo sheets.

Hence, the goal of this research is to obtain the embedding strength for bamboo mat board and bamboo strip board and compare these values with actual theoretical equations.

The part of the report hereafter is divided in four chapters: 2, 3, 4 and 5.

Chapter 2 describes the state of the art regarding lateral connections in wooden materials and the importance of the embedding strength property for wooden-based materials. It also gives theoretical derived equations for calculating the embedding strength for solid wood and plywood and equations for obtaining ultimate capacities for lateral-loaded nailed joints (annex 1).

Chapter 3 presents the experimental tests details such as test setup, specimen sizes, description of test apparatus, load and deformation measurements and so on.

The next chapter is about the obtained results and its respective analyses.

The last chapter gives final conclusions and recommendations.
2. STATE OF THE ART WITH REGARD TO EMBEDDING STRENGTH

2.1 American Approach [1]

Maximum lateral resistance and safe design load values of nails were based on an empirical method prior to 1991. Research conducted during the 80’s resulted in lateral resistance values that are based on a yield model theory.

Before 1991, the following formula was used:

\[ p = KD^{3/2} \]  

Where,

- \( p \) : lateral load per nail,
- \( K \) : coefficient (depending on density and type of fastener),
- \( D \) : diameter of nail.

The equation applies when the connected materials are approximately of the same density. The test loads were measured at joint slips of 0.38 mm. For ultimate loads, equation 1 can be increased 3.5 times for softwoods and 7 times for hard woods. The length of the nail in the wood receiving the point should be at least 10 times the diameter of nail for dense woods (more than 610 kg/m\(^3\) in density) and 14 times the diameter for woods with a density less than 420 kg/m\(^3\).

After 1991, a yield model theory based on the European approach is adopted. This model selects the worst case of yield modes based on different possibilities of wood bearing and nail bending. Figure 1 shows various combinations of wood-bearing and fastener-bending yields. Equations were developed for each of the failure modes and are shown in table 1. They depend on the dowel bearing strength (or embedding strength), dimensions of the wood members and the bending yield strength and diameter of the fastener. The dowel bearing strength of the wood is experimentally determined by compressing a dowel into a wood member. An empirical relation has been determined between bearing strength \( F_e \) and specific gravity of the wood \( G \) as:

\[ F_e = 114.5G^{1.84} \]

</table>

Definitions:

- $D$: rail, spike, or screw diameter, mm (in.) (for annularly threaded nails, $D$ is thread-root diameter; for screws, $D$ is either the shank diameter or the root diameter if the threaded portion of the screw is in the shear plane)
- $F_{en}$: dowel bearing stress of main member (member holding point), kPa (lb/in$^2$)
- $F_{es}$: dowel bearing stress of side member, kPa (lb/in$^2$)
- $F_{sb}$: bending yield stress of nail, spike, or screw, kPa (lb/in$^2$)
- $p$: penetration of nail or spike in main member, mm (in.)
- $t_s$: thickness of side member, mm (in.)
- $Z$: offset lateral yield strength
- $R_e$: $F_{es}/F_{en}$

\[
k_1 = -1 + \sqrt{2 + \frac{2F_{sb}(1 + 2R_e)D^2}{3F_{en}p^2}}
\]
\[
k_2 = -1 + \sqrt{2 + \frac{2F_{sb}(2 + R_e)D^2}{3F_{en}t_s^2}}
\]
\[
k_3 = -1 + \sqrt{2 + \frac{2F_{sb}(2 + R_e)D^2}{2F_{en}t_s^2}}
\]
2.2 European Approach

As said before, the American approach after 1991 was based on the European approach which is a model of bearing failure of the joint members or the simultaneous development of a bearing failure of the joint members and plastic hinge formation in the fastener. This theory is presented in annex 1 and is known as Johansen’s equations [2]. With this theory, ultimate capacities of lateral joints between wooden members can be calculated. The parameters needed to obtain these resistance values are (see figure 2):

1. The timber thickness and fastener penetrations ($t_1$ and $t_2$),
2. Embedding strength corresponding to $t_1$ ($f_{h,1}$),
3. Embedding strength corresponding to $t_2$ ($f_{h,2}$),
4. Diameter of the fastener ($d$) and,
5. Yield moment for fastener ($M_y$).

![Figure 2. Parameters needed for the embedding strength calculation.](image)

Looking at the equations of the different failure modes in annex 1, it can be noticed that the embedding strength ($f_{h}$) is a very important property of the connection system.

*Theoretical formulas for embedding strength according to Eurocode [3]:*

$$f_{h,k} = 0.082 \rho_k d^{-0.3}$$  \hspace{1cm} (3)
$$f_{h,k} = 0.082(1-0.01d)\rho_k$$  \hspace{1cm} (4)
$$f_{h,k} = 0.11\rho_k d^{-0.3}$$  \hspace{1cm} (5)
$$f_{h,k} = 0.11(1-0.01d)\rho_k$$  \hspace{1cm} (6)

Where,

$f_{h,k}$: Characteristic embedding strength in N/mm$^2$.
$d$: diameter of nail in mm.
$\rho_k$: characteristic density in kg/m$^3$.

Equation 3 is for nailed connections of solid wood without the use of predrilled holes.
Equation 4 is for nailed connections of solid wood using predrilled holes.
Equation 5 is for plywood connections without the use of predrilled holes.
Equation 6 is for plywood bolted connections which would be similar to nailed connections with predrilled holes.
3. EXPERIMENTAL TESTS

3.1 Test setup

The way of determining the embedding strength for nailed connections in plybamboo was based on the European Standard EN 383 [4] which is attached as Annex 2. However, the loading procedure was different. As can be seen in page 24, when 40% of the maximum load is reached, 30 seconds after it should be reduced to 10% of the maximum load and then increased again. The purpose of this procedure is to obtain the foundation modulus values (see equations 2 to 7 in page 25). This part was skipped because it was not of interest for the purpose of this research and as can bee seen in the curves in annex 4, if this change had been done it would not have had an influence on the maximum load.

3.2 Test specimens

The test specimens used were bamboo mat boards (MB) from India (12 mm thick and woven at 45 °, see figure 3) and bamboo strip boards (SB) from China (18 mm thick, three layers with the internal one perpendicular to the external ones, see figure 3). Some physical and mechanical properties of these materials can be seen in annex 3.

30 specimens of MB of 12x50x120 mm were tested as well as 30 specimens of SB of 18x50x120 mm. 5 mm nails were used for each of the 60 tests.

3.3 Equipment and test apparatus

The equipment used was quite simple. Since the size of the apparatus and specimens were rather small, the tests were able to be done in a compression machine with a load capacity of about 100 kN.

Figure 4 shows (a description of) the equipment and test apparatus used.
Figure 4. Equipment and test apparatus used.

Apparatus:

The test apparatus consists of different pieces of steel joined together in order to allow the positioning of the specimen and the LVDT’s (Linear variable differential transformers). These pieces of steel are numbered in figure 4 as:

11: Two parts acting as a platform of the whole apparatus.
8: Two steel blocks glued to 11 with a channel section on their sides in which 10 is going to fit. One of the blocks has a hole with a bolt that can tight 10 (figure 4).
7: One part acting as a connector between 8 and 6. It is screwed to 8 and glued to 6.
6: Two steel plates that give the appropriate space for the test specimen to move.
4b: Two steel plates screwed to 6 with half a circular hole in the center on which the nail is going to rest.

Test procedure:

1. The specimen is cut into size (120x50 mm). The thickness is the one of the sheet (12 mm for MB and 18 mm for SB). This size was determined according to the range of sizes given in annex 2 (see page 22) depending on the thickness of the sheet and nail diameter (See figure 5).
2. The specimen is predrilled with either a 4 mm, 4.5 mm or 5 mm hole. The location of the hole is the center of the specimen (figure 6).

![Figure 6. Drilling the hole in the specimen.](image)

3. The nail is placed into the specimen as straight as possible (the angle between the nail and the specimen should be approximately 90°). In order to achieve this, the nail was pushed by the drilling machine as shown in figure 7. This is possible because the part of the drilling machine that holds the drill could be closed producing a flat surface on which the nail was held. Then, the machine goes downwards pushing the nail into the specimen.

![Figure 7. Placing the nail into the specimen.](image)
4. The LVDT cores (figure 8a) were placed on the specimen at 5 mm from the bottom edge as shown in figure 8b.

Figure 8. (a) LVDT’s. (b) Placing LVDT’s on the specimen.

5. The LVDT bodies (9b in figure 4) are placed on the test apparatus with the help of a metal plate (number 10 in figure 4). 9b can move upwards and downwards through a hole in 10 and can be tight by a bolt (see green circle in figure 9).

6. The specimen is placed on the test apparatus (See figure 9).

Figure 9. Placing the specimen on the apparatus.
7. The steel plates named 4a in figure 4 are screwed to the plates 4b and the loading block is put above the specimen. Afterwards, the specimen and apparatus are placed on the compression machine in order to begin the test (figure 10).

3.4. Measurement of load and deflection

The load and deflection were measured every 5 seconds at a speed rate of 1 mm/min. The tests were stopped at a deflection of about 8-10 mm. Nevertheless, 5 mm was enough to obtain the maximum load (see Annex 2). The maximum load was defined as the load at a deflection of 5 mm.

Figure 10. Test ready to start.
4. Experimental results and analysis

Table 2 shows a summary of the experiments design. Three variables were combined: material, direction and predrilled hole. For each possible combination, 5 tests were done which gives 60 experimental tests in total.

**Total number of tests 60**

* 1: Bamboo Mat Board, 2: Bamboo Strip Board.
** 1: MB cut in the direction of the fibers, 2: MB cut as they are (woven into 45°), 3: SB with center ply perpendicular to the force, 4: SB with center ply parallel to the force.

The Load-Deflection diagrams for each combination are shown in annex 4.

The results of all the tests are presented in table A5.1 (See Annex 5).

In order to determine if there was a statistical significance for each of the factors on the embedding strength, a multifactor analysis of variance (ANOVA) for the embedding strength was done.

Firstly, the analysis was done with all the tests (60) comparing the factors hole and material (See Annex 5, statistical analysis #1). This analysis was made in order to corroborate if the material had an influence on the final result. Direction was not evaluated in this analysis because it is a material-dependant property. In table A5.2 can be seen that the P-value for material is less than 0.05 which means that there is a statistically significant effect on the embedding strength. The P-value for hole being larger than 0.05 (0.46) indicates that there is no statistically significant effect on the embedding strength. In other words, each material has a different embedding strength value independently from the size of the predrilled hole in the range of 4 and 5 mm.

The second analysis was done for material 1 (30 tests) comparing the factors direction and hole (annex 5, statistical analysis #2). The ANOVA analysis (table A5.4) showed that hole and direction do not have a statistically significant effect on the embedding strength since both P-values were larger than 0.05 (0.63 for direction and 0.32 for hole).

The last analysis (annex 5, statistical analysis #3) showed the same result as the previous one for material 2. In this case the P-values were 0.67 for direction and 0.29 for hole.

All the statistical analyses were done using the program STATIGRAPHICS Plus 4.0 [6]. All the tables and figures in Annex 5 are from the program except table A5.1.
Since hole and direction do not have a significant effect on the embedding strength of plybamboo, the embedding strength average for each material can be obtained. From table A5.3 in annex 5, 92.5 and 86.2 N/mm² were the mean embedding strength values for mat board and strip board respectively. The standard deviations for these values are 8.1 and 7.8 respectively. The 95% confidence intervals are 89.6-95.4 for MB and 83.4-89.2 for SB.

Table 3 compares different values of embedding strength using equations 2, 4 and 6 and the experimental values obtained from the tests. The densities used for MB and SB were 790 and 720 kg/m³ respectively (see annex 3). The diameter of the nail used for equations 4 and 6 was 5 mm. From the table it can be seen that the most accurate equation is equation 6 which is the one for bolted connections in plywood. It is clear that equation 4 gives the smaller values because it is only for solid wood connections. Equation 2 does not consider the diameter of the nail but is also only for wood. However, it gives higher values than equation 4. The difference between equation 6 and the obtained results is approximately 10%.

5. CONCLUSIONS AND RECOMMENDATIONS

- Based on the European Standard 383 test method (annex 2), the embedding strength of bamboo mat board, 12 mm thick, 790 kg/m³ of density, using predrilled holes between 4 and 5 mm diameter smooth round nails is around 89 and 96 N/mm² (92.5 in average) regardless of the direction of the grain.

- Based on the European Standard 383 test method (annex 2), the embedding strength of bamboo strip board, 18 mm thick, 720 kg/m³ of density, using predrilled holes between 4 and 5 mm diameter smooth round nails is around 83 and 89 N/mm² (86.2 in average) regardless of the direction of the grain.

- Equation (6) from Eurocode 5 could be conservatively used for calculating embedding strength values for plybamboo with different nail diameters.

- With the experimental results and statistical analysis was proved that the direction of the grain and size of the predrilled hole do not have an effect on the embedding strength for plybamboo and hence, its behavior is similar to that one of plywood and that density is the most important property affecting the embedding strength.

- More experimental tests should be carried out varying the nail diameter and thickness of the plywood in order to develop a corresponding equation for the embedding strength of plybamboo.

- Lateral joints tests could be carried out and the experimental results could be compared to those ones theoretically calculated using equation (6).

ANNEX 1

Johansen’s equations. Fasteners in single shear

In deriving Johansen’s ultimate load equations it is assumed that both the fastener and the timber are ideal rigid-plastic materials, e.g. the load-embedding characteristic for the timber is as shown in Figure 4. This approximation simplifies the analysis and makes little difference to the final result.

![Figure 4](image)

**Figure 4**  Simplified load-embedding characteristic.

The following notation is used:

- $t_1$ and $t_2$ are the timber thicknesses or fastener penetrations,
- $f_{b,1}$ is the characteristic embedding strength corresponding to $t_1$,
- $f_{b,2}$ is the characteristic embedding strength corresponding to $t_2$,
- $\beta = \frac{f_{b,2}}{f_{b,1}}$, where $f_{b,d} = \frac{k_{med} f_{b,d}}{\gamma_M}$ is the design value of embedding strength,
- $d$ is the diameter of fastener,
- $M'_{sa}$ is the characteristic yield moment for fastener,
- $M'_{sa} = \frac{M_{sa}}{\gamma_M}$ is the design value of fastener yield moment and
- $R_s$ is the design resistance per shear plane.

The numbering of the failure modes used in the following derivations follows that used by Johansen.
Failure mode 1b

From Figure 5

\[ R_d = f_{h1d} t_1 d \]

From Figure 6

\[ R_d = f_{h2d} t_2 d \]

\[ R_d = \beta f_{h1d} r_1 d \]

(2)

(3)

Figure 5  Mode 1b failure in $t_1$

Figure 6  Mode 1b failure in $t_2$

Failure mode 1a

\[ R_d = f_{h1d} d b_1 = f_{h2d} d b_2 = \beta f_{h1d} d b_1 \]

\[ b_1 = \beta b_2 \]

Moment at interface = \[ f_{h1d} d \left( \frac{b_1^2}{2} - a_1^2 \right) \]

= \[ f_{h2d} d \left( a_2^2 - \frac{b_2^2}{2} \right) \]

= \[ \beta f_{h1d} d \left( a_2^2 - \frac{b_2^2}{2} \right) \]

Equating and putting $b_2 = \frac{b_1}{\beta}$ gives:

\[ \frac{b_1^2}{2} \frac{\beta + 1}{\beta} = \beta a_2^2 + a_1^2 \]
\[ a_1 = \frac{r_1 - b_1}{2} \quad \text{and} \quad a_2 = \frac{r_2 - b_2}{2} = \frac{\beta r_2 - b_1}{2\beta} \]

Substitution gives:

\[ b_1^2 \left( \frac{1 + \beta}{\beta} \right) + 2 b_1 (t_1 + t_2) - (t_1^2 + \beta t_2^2) = 0 \]

Solving for \( b_1 \) gives:

\[ b_1 = \frac{t_1}{1 + \beta} \left[ \sqrt{\beta - 2 \beta^2 \left[ 1 + \frac{t_2}{t_1} + \left( \frac{t_2}{t_1} \right)^2 \right] - \beta \left( 1 + \frac{t_2}{t_1} \right)} \right] \]

\[ R_d = f_{h,1d} d b_1 \]

\[ R_d = \frac{f_{h,1d} d}{1 + \beta} \left[ \sqrt{\beta - 2 \beta^2 \left[ 1 + \frac{t_2}{t_1} + \left( \frac{t_2}{t_1} \right)^2 \right] - \beta \left( 1 + \frac{t_2}{t_1} \right)} \right] \]

Figure 8  Mode 2a failure.

Figure 9  Mode 2b failure.

Failure mode 2a (from Figure 8)

At \( M_{\text{max}} \) shear = 0

\[ f_{h,1d} d b_1 = f_{h,2d} d b_2 = \beta f_{h,1d} d b_2 \]

\[ b_1 = \beta b_2 \]

\[ M_{\text{xd}} = f_{h,2d} d b_2^2 + f_{h,1d} d (b_1 - a_1) \left( b_2 + \frac{b_1 + a_1}{2} \right) - f_{h,1d} d a_1 \left( b_1 + b_2 + \frac{3 a_1}{2} \right) \]

Substituting \( f_{h,2d} = \beta f_{h,1d} \) and \( a_1 = \frac{t_1 - b_1}{2} \) gives:

\[ b_1^2 + \frac{t_1}{2} \frac{2}{2 + \beta} b_1 - \frac{\beta t_1^2}{2 + \beta} f_{h,1d} d \frac{4 \beta}{2 + \beta} = 0 \]
then \( b_1 = \frac{t_1}{2 + \beta} \left[ \frac{2 \beta (1 + \beta) + \frac{4 \beta(2 + \beta) M_{yd}}{f_{h,1,d} d t^2_2}}{f_{h,1,d} d t^2_2} \right] \)

and \( R_d = f_{h,1,d} d b_1 \)

\[
R_d = \frac{f_{h,1,d} d t_1}{2 + \beta} \left[ \frac{2 \beta (1 + \beta) + \frac{4 \beta(2 + \beta) M_{yd}}{f_{h,1,d} d t^2_2}}{f_{h,1,d} d t^2_2} \right] \]  

(5)

Failure mode 2b (from Figure 9)

As before \( b_1 = \beta b_2 \)

\[
M_{yd} = f_{h,1,d} d \left[ -\frac{t_2^2}{2} + \beta b_2 \left( \frac{b_1 + b_2}{2} \right) + \beta a_2 \left( \frac{b_1 + t_2 - 3 a_2}{2} \right) - \beta a_2 \left( \frac{b_1 + t_2 - a_2}{2} \right) \right]
\]

Substituting \( b_2 = \beta b_2 \) and \( a_2 = \frac{t_2 - b_2}{2} \) gives:

\[
b_2 = \frac{\beta}{2} \frac{4 t_2 b_2}{\beta (2 \beta + 1)} - \frac{\beta t_2^2}{4 f_{h,1,d} d} \left( \frac{4 M_{yd}}{\beta (2 \beta + 1)} \right) = 0
\]

\[
b_2 = \frac{-t_2}{2 \beta + 1} + \sqrt{\frac{t_2^2}{(2 \beta + 1)^2} + \frac{t_2^2}{2 \beta + 1} + \frac{4 M_{yd}}{f_{h,1,d} d \beta (2 \beta + 1)}}
\]

\[
R_d = \beta f_{h,1,d} d b_2
\]

\[
R_d = \frac{f_{h,1,d} d t_2}{1 + 2 \beta} \left[ \frac{2 \beta^2 (1 + \beta) + \frac{4 \beta(1 + 2 \beta) M_{yd}}{f_{h,1,d} d t^2_2}}{f_{h,1,d} d t^2_2} \right]
\]  

(6)

Failure Mode 3 (from Figure 10)

\[
M_{yd} + M_{yd} = f_{h,1,d} d b_1 \left( \frac{b_1}{2} + \frac{b_2}{2} \right) - \beta f_{h,1,d} d b_2 \frac{b_2^2}{2}
\]

\[
b_2 = \frac{b_1}{\beta}
\]

\[
b_1 = \frac{2 M_{yd}}{f_{h,1,d} d} \left( \frac{2 \beta}{1 + \beta} \right)
\]
Johansen’s equations may also be derived using the Virtual Work approach (Aune and Patton-Mallory, 1986).

**Additional resistance**

As the fastener deforms under load axial forces can develop for failure modes 2 and 3. These are caused by friction between the fastener and the timber and also by the constraints produced by the heads of nails and the washer assemblies in bolts.

The force in the inclined part of the fastener will have a component parallel to the applied load and will, therefore, enhance the resistance. EC5 takes this effect into account by enhancing the resistance for modes 2 and 3 failures by 10 per cent.

In an actual joint the load carrying capacity will correspond to the lowest value obtained for $R_d$ by substituting into the full set of equations. The equation giving the lowest capacity will also identify the failure mode.
ANNEX 2

Timber structures — Test methods — Determination of embedding strength and foundation values for dowel type fasteners

This European Standard was approved by CEN on 1993-07-15. CEN members are bound to comply with the CEN/CENELEC Internal Regulations which stipulate the conditions for giving this European Standard the status of a national standard without any alteration.

Up-to-date lists and bibliographical references concerning such national standards may be obtained on application to the Central Secretariat or to any CEN member.

This European Standard exists in three official versions (English, French, German). A version in any other language made by translation under the responsibility of a CEN member into its own language and notified to the Central Secretariat has the same status as the official versions.

CEN members are the national standards bodies of Austria, Belgium, Denmark, Finland, France, Germany, Greece, Iceland, Ireland, Italy, Luxembourg, Netherlands, Norway, Portugal, Spain, Sweden, Switzerland and United Kingdom.

Ref. No. EN 383 : 1993 E
Foreword

This European Standard was prepared by CEN/TC 124 "Timber structures". It was approved for the CEN final voting by the TC on 9th December 1991.

This standard is one of a series of standards for test methods for building materials and components. It was prepared by a working group under the convenership of NSAI.

NOTE: It is recommended desirable to maintain the same clause numbers consistently throughout the series of standards. Consequently, some clauses are void in this edition of this standard, but it is envisaged that future editions may need to include a text in these clauses.

European Standard shall be given the status of a national standard, either by publication of an identical text or by endorsement, at the latest by January 1994, and conflicting national standards shall be withdrawn at the latest by January 1994.

The standard was approved and in accordance with the CEN/CENELEC Internal Regulations, the following countries are bound to implement this European Standard: Austria, Belgium, Denmark, Finland, France, Germany, Greece, Iceland, Ireland, Italy, Luxembourg, Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, United Kingdom.

No existing European Standard is superseded.

1 Scope
This standard specifies laboratory methods of determining the embedding strength and
embedding value of solid timber, glued laminated timber, and wood-based sheet products with dowel
type fasteners.

2 Normative references
None.

3 Definitions
For the purposes of this standard, the following definitions apply.

3.1 dowel type fastener
Bolt, nail, dowel or the like with plain or patterned
surfaces.

3.2 Embedding strength
Average compressive stress at maximum load in a
piece of timber or wood-based sheet product under the
action of a still linear force. The fastener's
axis is perpendicular to the surface of the timber.
The fastener is loaded perpendicular to its axis.

3.3 maximum load
Maximum load measured before the deformation of
the specimen has reached the deformation limit.

3.4 fastener section dimension
1) Actual diameter of a plain round fastener; or
2) Shank diameter of a profiled fastener; or
3) Length of one side of the section of a square
fastener; or
4) Minimum dimension of the section of an oval or
rectangular fastener.

4 Symbols
\( d \) fastener section dimension, in
millimetres
\( F \) load, in newtons
\( F_{\text{max}} \) maximum load, in newtons
\( F_{\text{max,est}} \) estimated maximum load, in newtons
\( j_b \) embedding strength, in newtons per
square millimetre
\( j_{b,\text{est}} \) estimated embedding strength, in
newtons per square millimetre
\( E_c \) elastic foundation modulus, in newtons per
cubic millimetre
\( E_{f_1} \) initial foundation modulus, in newtons per
cubic millimetre
\( E_{f_2} \) foundation modulus, in newtons per
cubic millimetre
\( t \) thickness, in millimetres
\( w \) indentation or deformation, in
millimetres
\( w_0 \) elastic deformation, in millimetres
\( w_0 \) initial deformation, in millimetres
\( w_{\text{mod}} \) modified initial deformation, in
millimetres
\( w_0 \) deformation of the test apparatus at any
given load, in millimetres

5 Requirements
The fasteners and the timber, glued laminated
timber, or wood-based sheet product shall be, as far
as possible, of the minimum quality allowed by the
relevant specification.

6 Test method
6.1 Principle
The test shall be carried out on the test piece and
using the apparatus shown in figure 1. It is a
principle of this test to avoid bending of the
fastener under test.
The fastener is loaded perpendicular to its axis
through a steel loading apparatus and the load and
the corresponding indentation or deformation is
measured, see figure 1.
The loading may be either in compression, see
figure 2a, or in tension, see figure 2b. For solid
timber and layered wood products with only one
grain direction the loading may be either parallel to
the grain, see figures 2a and 2b or compression
perpendicular to the grain, see figure 2c.
NOTE. The principles of this standard may not be used for other
angles between the load and the grain.

6.2 Test pieces
The test piece is a rectangular prism of wood or
wood-based sheet product with a fastener placed
with its axis perpendicular to the surface of the
prismatic test piece. The sizes of the test pieces are
given in table 1.
NOTE. The thickness should be in the range 1.5d to 4d in
order to comply with the principle of the test.
For wood-based sheet products, the thickness of
the test piece shall be the thickness of the panel as
produced.
Report: Embedding strength of plybamboo. G.E. González

Measurements given in figure 2 are dependent on d, where d is defined; see clause 3.4.
6.3 Apparatus
The test apparatus shall be such that no friction between test plates and test pieces may influence the measurements. In addition to equipment for measuring the geometry, moisture content, etc., of the test pieces, the following shall be available:

a) loading equipment capable of applying and continuously recording the load to an accuracy of ± 1 % of the load applied to the test piece or, for loads less than 10 % of the maximum load applied to the piece, with an accuracy of ± 0.1 % of the maximum load;
b) equipment to continuously record the displacement of the fasteners in the wood with an accuracy of ± 1 % of the displacement, or for displacement less than 5 mm ± 0.02 mm.

NOTE. The equipment would ensure that all conditions, etc., have no influence on the measurements.

6.4 Preparation of test pieces
Before placing the fastener, the wood material shall be conditioned to constant mass in an environment having a relative humidity of (65 ± 5)% and a temperature of (20 ± 2) °C. After fabrication the test piece shall be conditioned again in the same environment. Constant mass is considered to be attained when the results of two successive weighings, carried out at an interval of 6 h, do not differ by more than 0.1 % of the mass of the test piece.

NOTE. For particular investigations it may be appropriate to condition the test piece to other moisture conditions both before and after placing the fastener; if other climatic conditions are used, they are to be reported.

6.5 Procedure
6.5.1 Apparatus calibration
Initially the stiffness characteristic of the loading apparatus shall be determined. A steel specimen with a tight-fitting pin of the same diameter as the fastener shall be placed in the apparatus and the load deformation curve shall be determined as described in 6.5.8.

6.5.2 Placing of fastener
The diameter of the fastener and the thickness of the test piece shall be measured in millimetres to an accuracy of 1 %.

The fastener shall be placed in the same way as would be used in practice (e.g. predrilling or no-preboring for nails, tight-fitting holes for dowels, oversized holes for bolts).

NOTE. To ensure that the axis of the fastener is perpendicular to the surface of the test piece a guide should be used.

6.5.3 Placing of test piece in apparatus
The test piece shall be placed symmetrically in the test apparatus. The load shall be applied in the axis of the test piece.

6.5.4 Estimation of maximum load
The estimated maximum load \( F_{\text{max,est}} \) shall be determined on the basis of experience, calculation or preliminary tests.

NOTE. The estimation shall be adjusted as described in 6.8.2.

6.5.5 Application of load
The loading procedure as shown in figure 3 shall be followed except that, for particular tests, the preload cycle up to 0.4 \( F_{\text{max,est}} \) may be omitted with a corresponding adjustment to the total testing time. The load shall be increased to 0.4 \( F_{\text{max,est}} \) and maintained for 30 s.

The load shall then be reduced to 0.1 \( F_{\text{max,est}} \) and maintained for 30 s. Thereafter the load shall be increased.

The test shall then be stopped either when the maximum load is reached or when the deformation is \( w_0 + 5 \text{ mm} \).

The load shall be increased or decreased at a constant rate of loading-head movement. The load shall be so adjusted that the maximum load is reached within (300 ± 120) s.

6.5.6 Recording of deformation
The deformations \( w_0, w_{0.1}, w_{0.4}, w_{0.8}, w_{1.2}, w_{2.4}, w_{4.8} \) and \( w_{5.0} \) corresponding to the points 01, 04, 14, 21, 24, 26 and 28 as shown in figure 4 shall be recorded for each test piece to give the load deformation curve. The deformation at maximum load \( F_{\text{max}} \) shall also be recorded.

When a load deformation curve is not available, measurements of deformation should be taken at each 0.1 \( F_{\text{max,est}} \) increment of load, see figure 3.

6.5.7 Determination of density and moisture content
Determine the density and moisture content of the timber or wood based sheet products.
Figure 3. Loading procedure
6.6 Results

6.6.1 Calculations

The embedding strength \( f_e \) and the estimated embedding strength \( f_{e,est} \) shall be calculated to an accuracy of \( 1\% \) using the following formulae:

\[
\begin{align*}
\dot{f}_e &= \frac{F_{\text{max}}}{dt} \\
\dot{f}_{e,est} &= \frac{F_{\text{max,est}}}{dt}
\end{align*}
\]  

From the recorded measurements the following values, if relevant, shall be calculated:

- initial deformation:
  \( w_0 = \frac{2}{3} (w_{14} + w_{20} - w_{11} - w_{21}) \)  

- modified initial deformation:
  \( w_{h,mod} = \frac{2}{3} (w_{14} - w_{11}) \)  

- elastic deformation:
  \( u_e = \frac{0.4}{3} \left( w_{14} + w_{20} - w_{11} - w_{21} \right) \)  

- initial foundation modulus:
  \( K_0 = \frac{0.4 \dot{f}_{e,est}}{\dot{w}_0} \)  

- foundation modulus:
  \( K_0 = \frac{0.4 \dot{f}_{e,est}}{w_{h,mod}} \)  

- elastic foundation modulus:
  \( K_0 = \frac{0.4 \dot{f}_{e,est}}{u_e} \)  

- deformation at 0.6 \( F_{\text{max}} \):
  \( w_{0.6} \)  

- deformation at 0.8 \( F_{\text{max}} \):
  \( w_{0.8} \)

The measured load deformation curve shall, if relevant, be corrected as shown in figure 5.
6.6.2 Adjustments

If, during the execution of the tests, the mean value of the maximum load of the tests already carried out deviates by more than 20% from the estimated value, this value shall be adjusted correspondingly for subsequent tests. The values of maximum load already determined may be accepted without adjustment as part of the final results. In this case, the values of deformation and foundation moduli determined in equations (2) to (7) shall be adjusted to correspond to the adjusted values of the estimated value.

6.7 Test report

The test report shall include the following:

a) sampling procedure;
b) specification and quality of material; species, density, grain direction or grain orientation, strength properties;
c) type, diameter, strength characteristics and surface treatment of the fastener (including anticorrosion protection);
d) size of the test pieces, diameter of the hole and manner of placing the fastener in the specimen;
e) conditioning of test pieces before and after preparation, moisture content at test;
f) test results and information regarding adjustments, mean values and standard deviations, and descriptions of the modes of failure.

(1) According to ASTM D3500-90.
(2) According to ASTM D3501-86, the first value corresponds to the compressive strength parallel to the grain and the second perpendicular to the grain.
(3) According to ASTM D3043-87.
(4) According to British Standard #373.

The values for MB were obtained from reference [5] and they were based on the ASTM standard procedures according to Dr. H.N. Jagadesh from IPIRTI [5]. The values for SB were provided by Mr. Samuel Yao from Qingfeng Bamboo Flooring (Internet address: http://www.china-qingfeng.com).

All the data represent mean values from certain number of tests.
ANNEX 4

Notation:

ES: Embedding strength test, the first number indicates the material. Number 1 is for bamboo mat board and number 2 for bamboo strip board. The second number indicates the direction of the fiber as explained in page 10. The third and last number indicates the size of the hole in mm.

$f_{h,\text{mean}}$: Embedding strength mean.

$K_{\text{mean}}$: Rigidity of the test.

SD: Standard deviation.

Statistical analysis #1

Notation:

ES: Embedding strength

Analysis Summary

Dependent variable: ES
Factors:
  Hole
  Material

Number of complete cases: 60

The StatAdvisor
--------------
This procedure performs a multifactor analysis of variance for ES. It constructs various tests and graphs to determine which factors have a statistically significant effect on ES. It also tests for significant interactions amongst the factors, given sufficient data. The F-tests in the ANOVA table will allow you to identify the significant factors. For each significant factor, the Multiple Range Tests will tell you which means are significantly different from which others. The Means Plot and Interaction Plot will help you interpret the significant effects. The Residual Plots will help you judge whether the assumptions underlying the analysis of variance are violated by the data.
Table A5.2 ANOVA table for ES with hole and material as factors.

</tr>
</tbody>
</table>

All F-ratios are based on the residual mean square error.

The StatAdvisor
---------------

The ANOVA table decomposes the variability of ES into contributions due to various factors. Since Type III sums of squares (the default) have been chosen, the contribution of each factor is measured having removed the effects of all other factors. The P-values test the statistical significance of each of the factors. Since one P-value is less than 0.05, this factor has a statistically significant effect on ES at the 95.0% confidence level.

The StatAdvisor
---------------

This table shows the mean ES for each level of the factors. It also shows the standard error of each mean, which is a measure of its sampling variability. The rightmost two columns show 95.0% confidence intervals for each of the means. You can display these means and intervals by selecting Means Plot from the list of Graphical Options.
