0 Introduction

In this paper we design a parallel program for computing the Dirichlet Convolution of two
arithmetical functions. We believe that the program derivation we present is easy to under­
stand and is, thereby, a nice example of our method for designing parallel programs. Programs
are derived from their formal specification in a calculational manner. Correctness by design
is our main objective, whereas other methods afterwards require a verification of the con­
structed algorithm.

The problem of designing a parallel program for Dirichlet Convolution was originally posed
by Tom Verhoeff in [5]. Solutions for computing the Dirichlet Convolution can be found in
[0] and [3]. These solutions resemble our solution; the program derivations, however, are
completely different.

The program we derive is a program with fine-grained parallelism. We do not discuss methods
to enlarge the grain-size. Our main goal is to show that our design method can be applied to
non-trivial examples as easily as to simple examples.

This paper is organized as follows. In section 1 the Dirichlet Convolution is defined and a par­
allel program is derived for computing the Dirichlet Convolution of two arbitrary arithmetical
functions. Section 2 deals with the inverse convolution problem. A parallel program for the
inverse convolution problem turns out to be almost identical to the program for Dirichlet
Convolution. The Möbius function is an instance of the inverse convolution problem. A par­
allel program for this function is discussed in section 3. Our program for the Möbius function
differs from Tom Verhoeff’s program [5].

The notation we use has been adopted from [4].

1 Dirichlet Convolution

In this section we give a definition of Dirichlet Convolution. Next, we generalize this definition
and obtain an expression for which we derive a recurrence relation. The program we derive
1 DIRICHLET CONVOLUTION

consists of a network of cells that communicate with each other by message passing over unidirectional channels. By applying the above mentioned recurrence relation, we derive relations for the individual communications along the channels. These relations impose requirements upon the communication behavior of the cells. After finding a communication behavior that satisfies these requirements and that introduces minimal buffering, we present the program text. A short complexity analysis of the program concludes this section.

For an introduction to the theory of arithmetical functions we refer to [2]. We consider arithmetical functions to be functions defined on the positive integers and that have the integers as their range. The Dirichlet Convolution of two arithmetical functions $F$ and $G$, denoted by $F \ast G$, is defined as

$$(F \ast G)(n) = (\mathbb{S} \ p, q : p \ast q = n \land 1 \leq p \land 1 \leq q : F(p) \ast G(q))$$

for $n \geq 1$.

In this definition, the summation ranges over a non-empty domain that is symmetric in $p$ and $q$. In the program derivation, we shall maintain this symmetry. We do so because other problems (e.g. dynamic programming [1]) show that destroying symmetry often leads to inefficient programs.

For the derivation of our program we prefer a slightly different (but equivalent) definition of $F \ast G$:

$$(F \ast G)(n) = (\mathbb{S} \ p, q : p \ast q = n \land (\sqrt{n} \leq p \lor \sqrt{n} \leq q) : F(p) \ast G(q))$$

We generalize this expression by introducing an additional variable. For $0 \leq m \leq n$, expression $Q(m, n)$ is defined as

$$Q(m, n) = (\mathbb{S} \ p, q : p \ast q = n \land (\sqrt{n} \leq p \lor \sqrt{n} \leq q \leq m) : F(p) \ast G(q))$$

Notice that expression $Q(m, n)$ is defined in the context of arithmetical functions $F$ and $G$.

Taking $m = n$, we then have $Q(n, n) = (F \ast G)(n)$. Hence, computing the Dirichlet Convolution of two arithmetical functions can be done by evaluating expression $Q$. We now derive a recurrence relation for $Q(m, n)$, since evaluating $Q(n, n)$ involves evaluation of partial sums $Q(m, n)$.

For $0 \leq m < \sqrt{n}$

$$Q(m, n) = 0$$

and for $\sqrt{n} \leq m + 1 \leq n$, we derive

$$Q(m + 1, n) = \{ \text{ def. } Q \}$$

$$= (\mathbb{S} \ p, q : p \ast q = n \land (\sqrt{n} \leq p \leq m + 1 \lor \sqrt{n} \leq q \leq m + 1) : F(p) \ast G(q))$$

$$= \{ \sqrt{n} \leq m + 1 \}$$

$$= (\mathbb{S} \ p, q : p \ast q = n \land (\sqrt{n} \leq p \lor \sqrt{n} \leq q \leq m \lor p = m + 1 \lor q = m + 1) : F(p) \ast G(q))$$

$$= \{ \text{ domain split } \}$$
\[ (S \ p, q : p \times q = n \land (\sqrt{n} \leq p \leq m \lor \sqrt{n} \leq q \leq m) : F(p) \ast G(q)) \]
\[ + (S \ p, q : p \times q = n \land p = m + 1 \land q = m + 1 : F(p) \ast G(q)) \]
\[ + (S \ p, q : p \times q = n \land p \neq q \land (p = m + 1 \lor q = m + 1) : F(p) \ast G(q)) \]
\[ = \{ \text{def. } Q \} \]
\[ Q(m, n) \]
\[ + \text{ if } (m + 1)^2 = n \rightarrow F(m + 1) \ast G(m + 1) \]
\[ \text{ if } (m + 1)^2 \neq n \land (m + 1 \mid n) \rightarrow F(m + 1) \ast G(n/(m + 1)) \]
\[ \text{ if } -(m + 1 \mid n) \rightarrow 0 \]

where \( k \mid n \) denotes \( k \) divides \( n \), i.e. \( n \mod k = 0 \).

We rewrite this recurrence relation for \( Q(m, n) \)

\[ Q(0, n) = 0 \]
\[ Q(m + 1, n) = Q(m, n) \]
\[ + \text{ if } (m + 1)^2 < n \lor -(m + 1 \mid n) \rightarrow 0 \]
\[ \text{ if } (m + 1)^2 = n \rightarrow F(m + 1) \ast G(m + 1) \]
\[ \text{ if } (m + 1)^2 > n \land (m + 1 \mid n) \rightarrow F(m + 1) \ast G(n/(m + 1)) \]
\[ \text{ if } -(m + 1 \mid n) \rightarrow 0 \]

for \( 0 \leq m < n \).

We now have a recurrence relation for \( Q(m, n) \) which we use in the program derivation that follows.

The program we derive consists of a linear network of cells (see fig. 0). Cell 0 is fed with two arithmetical functions along two input channels \( f_0 \) and \( g_0 \):

\[ f_0(i) = F(i + 1) \]
\[ g_0(i) = G(i + 1) \]

for \( i \geq 0 \).

Cell 0 also communicates with the environment by means of output channel \( b_0 \), which satisfies
1 DIRICHLET CONVOLUTION

\[ b_0(i) = (F \ast G)(i + 1) \]

for \( i \geq 0 \).

Given this definition, the first communication along channel \( b_0 \) satisfies

\[
\begin{align*}
    b_0(0) &= \{ \text{def. } b_0 \} \\
    (F \ast G)(1) &= \{ \text{def. } F \ast G \} \\
    F(1) \ast G(1) &= \{ \text{def. } f_0 \text{ and } g_0 \} \\
    f_0(0) \ast g_0(0)
\end{align*}
\]

and for \( i \geq 0 \) we have

\[
\begin{align*}
    b_0(i + 1) &= \{ \text{def. } b_0 \} \\
    (F \ast G)((i + 1) + 1) &= \{ \text{def. } Q \} \\
    Q(i + 1, (i + 1) + 1) &= \{ \text{recurrence relation for } Q; \text{ using } (i + 2)^2 > i + 2 \text{ and } i + 2 \mid i + 2 \} \\
    Q(i + 1, (i + 1) + 1) + F((i + 1) + 1) \ast G(1) + F(1) \ast G((i + 1) + 1) &= \{ \text{def. } f_0 \text{ and } g_0 \} \\
    Q(i + 1, (i + 1) + 1) + f_0(i + 1) \ast g_0(0) + f_0(0) \ast g_0(i + 1)
\end{align*}
\]

On account of this expression, we decide that cell 1 computes \( Q(i + 1, (i + 1) + 1) \) and sends the result to cell 0 along channel \( b_1 \). Generalizing, output channel \( b_j \) of cell \( j \) \((j \geq 1)\) satisfies

\[
b_j(i) = Q(i + 1, i + 1 + j)
\]

for \( i \geq 0 \). Notice that this relation also holds for \( j = 0 \). On account of this observation, we expect that, later on, matching the communication behaviors of cell 0 and cell 1 will not cause any problem.

Summarizing, the values communicated along channel \( b_0 \) satisfy

\[
\begin{align*}
    b_0(0) &= f_0(0) \ast g_0(0) & \text{(0)} \\
    b_0(i + 1) &= b_1(i) + f_0(i + 1) \ast g_0(0) + f_0(0) \ast g_0(i + 1) & \text{(1)}
\end{align*}
\]

From now on we consider cell \( j \) for \( j \geq 1 \).

The first communication along channel \( b_j \) satisfies

\[
\begin{align*}
    b_j(0) &= \{ \text{def. } b_j \} \\
    Q(1, 1 + j)
\end{align*}
\]
1 DIRICHLET CONVOLUTION

\[
\begin{align*}
&= \{ \text{recurrence relation for } Q; Q(0, 1 + j) = 0; 1^2 < j + 1 \} \\
&= 0
\end{align*}
\]

and for \( i \geq 0 \) we have

\[
\begin{align*}
b_j(i + 1) &= \begin{cases}
\text{def. } b_j \\
Q((i + 1) + 1, (i + 1) + 1 + j)
\end{cases} \\
&= \begin{cases}
\text{recurrence relation for } Q; (i + 2 | i + j + 2) \equiv (i + 2 | j) \\
Q(i + 1, i + 1 + (j + 1))
\end{cases}
\quad + \text{ if } (i + 2)^2 < i + j + 2 \vee -(i + 2 | j) \rightarrow 0 \\
&\quad \quad \quad \left| (i + 2)^2 = i + j + 2 \rightarrow F(i + 2) \ast G(i + 2) \right.
\quad \quad \quad \left| (i + 2)^2 > i + j + 2 \wedge (i + 2 | j) \rightarrow F(i + 2) \ast G((i + j + 2)/(i + 2)) + F((i + j + 2)/(i + 2)) \ast G(i + 2) \right.
\end{align*}
\]

\[\text{fl}\]

Thus, for the \((i + 1)\)-th communication along channel \( b_j \) cell \( j \) should have at its disposal the values of: \( Q(i + 1, i + 1 + (j + 1)), F(i + 2), G(i + 2), F(1 + j/(i + 2)), \) and \( G(1 + j/(i + 2)) \). On account of the definition of channel \( b_j \), the \( i \)-th communication along channel \( b_{j+1} \) equals \( Q(i + 1, i + 1 + (j + 1)) \).

For \( F(1 + j/(i + 2)), F(i + 2), G(i + 2), \) and \( G(1 + j/(i + 2)) \) we introduce four input channels for cell \( j \): respectively \( e_j, f_j, g_j, \) and \( h_j \). Just like the definition of input channels \( f_0 \) and \( g_0 \), we define

\[
\begin{align*}
f_j(i) &= F(i + 1) \\
g_j(i) &= G(i + 1)
\end{align*}
\]

for \( i \geq 0 \).

Although, according to above derivation for \( b_j(i + 1), f_j(i) \) (and \( g_j(i) \) similarly) need only to be specified for indices \( i \) satisfying \( (i + 1)^2 \geq i + j + 1 \), we have specified \( f_j(i) \) for all natural \( i \).

For the specification of channel \( e_j \) and \( h_j \), however, we are more liberal, viz.

\[
\begin{align*}
e_j(i) &= F(1 + j \div (i + 1)) \\
h_j(i) &= G(1 + j \div (i + 1))
\end{align*}
\]

for all natural \( i \) satisfying \( (i + 1)^2 > (i + j + 1) \).

Actually, we have restricted ourselves a little, since \( e_j(i) \) (and \( h_j(i) \) similarly) need only be specified for indices \( i \) that also satisfy \( (i + 1 | j) \). In the sequel, we explicitly use the fact that \( e_j(i) \) is specified only for \( i \) satisfying \( (i + 1)^2 > (i + j + 1) \).

Now, communications along channel \( b_j \) are implemented by

\[
\begin{align*}
b_j(0) &= 0 \\
b_j(i + 1) &= b_{j+1}(i) \\
&\quad + \text{ if } (i + 2)^2 < i + j + 2 \vee -(i + 2 | j) \rightarrow 0 \\
&\quad \quad \quad \left| (i + 2)^2 = i + j + 2 \rightarrow f_j(i + 1) \ast g_j(i + 1) \right.
&\quad \quad \quad \left| (i + 2)^2 > i + j + 2 \wedge (i + 2 | j) \rightarrow f_j(i + 1) \ast h_j(i + 1) + e_j(i + 1) \ast g_j(i + 1) \right.
\end{align*}
\]

\[\text{fl}\]
Next, we turn our attention to the implementation of input channels $e_j, f_j, g_j, h_j$. On behalf of the symmetry between channels $e_j$ and $h_j$, and between channels $f_j$ and $g_j$, we only discuss the implementation of channels $e_j$ and $f_j$.

We are free to choose from which cell, either from cell $(j-1)$ or from cell $(j+1)$, cell $j$ receives inputs along channels $e_j$ and $f_j$. It turns out that the first choice, values along channel $e_j$ are sent from cell $(j-1)$ to cell $j$, is a good one. In particular, the fact that cell 0 can easily generate the values to be sent along channels $e_1$ and $f_1$ often indicates an appropriate choice.

Communications along channels $e_1$ and $f_1$ are sent by cell 0 and received by cell 1. Therefore, cell 0 must be able to compute both $e_1(i)$ and $f_1(i)$ for all natural $i$.

By definition, for all natural $i$: $f_1(i) = f_0(i)$.

The value of $e_1(i)$ is only specified for natural $i$ satisfying $(i + 1)^2 > i + 2$, i.e. for $i \geq 1$. We are free to choose an appropriate value for $e_1(0)$. For $i \geq 1$:

\[
\begin{align*}
e_1(i) &= \{ \text{def. } e_j \} \\
&= F(1 + 1 \text{ div } (i + 1)) \\
&= \{ i \geq 1 \text{ implies } 1 \text{ div } (i + 1) = 0 \} \\
&= F(1) \\
&= \{ \text{def. } f_0 \} \\
f_0(0)
\end{align*}
\]

An appropriate choice for the value of $e_1(0)$, now, is $e_1(0) = f_0(0)$, of course.

We proceed by calculating $e_{j+1}$ and $f_{j+1}$ for all $j \geq 1$ and $i \geq 0$. Since communications along channel $f_{j+1}$ are very easy to implement, viz. $f_{j+1}(i) = f_j(i)$, we focus our attention on $e_{j+1}(i)$.

In the calculation of $e_{j+1}$ we use two properties of the div-operator:

Property:
For $j \geq 1$ and $i \geq 0$:

0. If $-(i + 1 \mid j + 1)$, then $(j + 1) \text{ div } (i + 1) = j \text{ div } (i + 1)$.

1. If $(i + 1 \mid j + 1)$ and, moreover, $(i + 1)^2 > i + 2$, then $(j + 1) \text{ div } (i + 1) = j \text{ div } i$.

Proof:
Let $q = (j + 1) \text{ div } (i + 1)$ and $r = (j + 1) \text{ mod } (i + 1)$.

Then, by definition, $(j + 1) = q \ast (i + 1) + r \land 0 \leq r < i + 1$.

0. We derive

\[
\begin{align*}
j + 1 &= q \ast (i + 1) + r \land 0 \leq r < i + 1 \\
&= \{ \text{arithmetic} \} \\
j &= q \ast (i + 1) + (r - 1) \land -1 \leq (r - 1) < i \\
&= \{ -(i + 1 \mid j + 1) \text{ implies } r \neq 0 \} \\
j &= q \ast (i + 1) + (r - 1) \land 0 \leq (r - 1) < i
\end{align*}
\]
Hence, \((j + 1) \text{ div } (i + 1) = q = j \text{ div } (i + 1)\).

1. We derive
\[
\frac{(j + 1)}{(i + 1)} = \begin{cases} \text{arithmetic} \\ \frac{(i + j + 2)}{(i + 1)} - 1 \end{cases} < \begin{cases} (i + 1)^2 > i + j + 2 \end{cases} i
\]

From \(j + 1 \neq 0\) and \(j + 1 = q \ast (i + 1)\), we infer \(q \neq 0\). Hence, \(q\) satisfies \(1 \leq q < i\).
Since in this case \(j = q \ast i + (q - 1)\) and \(0 \leq (q - 1) < i\), we conclude that \((j + 1) \text{ div } (i + 1) = q = j \text{ div } i\).

\[
\square
\]

Notice that the second premise in the second property reflects the condition which we imposed on the specification of \(e_{j+1}\).

We now derive a relation for \(e_{j+1}(i)\). Since \(e_{j+1}(i)\) has only been specified for indices \(i\) satisfying \((i + 1)^2 > i + j + 2\) we have
\[
e_{j+1}(i) = \begin{cases} \text{def. } e_j \end{cases} F(1 + (j + 1) \text{ div } (i + 1)) = \begin{cases} \text{property above} \\ \text{if } \neg(i + 1 | j + 1) \rightarrow F(1 + j \text{ div } (i + 1)) \\ (i + 1 | j + 1) \rightarrow F(1 + j \text{ div } i) \end{cases}
\]
\[
e_{j+1}(i) = \begin{cases} \text{def. } e_j; (i + 1)^2 > i + j + 2 > i + j + 1 \\ \text{if } \neg(i + 1 | j + 1) \rightarrow e_j(i) \\ (i + 1 | j + 1) \land i^2 > i + j \rightarrow e_j(i - 1) \\ (i + 1 | j + 1) \land i^2 \leq i + j \rightarrow F(1 + (j + 1)/(i + 1)) \end{cases}
\]

Note that \(e_j(i - 1)\) is only specified for \(i^2 > i + j\). For \(i\) and \(j\) satisfying both \((i + 1 | j + 1)\) and \(i^2 \leq i + j\) and \((i + 1)^2 > i + j + 2\), we therefore have to determine \(F(1 + (j + 1)/(i + 1))\).

Since
\[
i^2 \leq i + j \land (i + 1)^2 > (i + 1) + (j + 1) = \begin{cases} \text{arithmetic} \end{cases} i^2 - i + 1 \leq j + 1 < i \ast (i + 1) = \begin{cases} \text{arithmetic} \end{cases} (i - 2) + 3/(i + 1) \leq (j + 1)/(i + 1) < i \Rightarrow \begin{cases} (i + 1 | j + 1) \end{cases} (j + 1)/(i + 1) = i - 1
\]
we conclude that in this case \( F(1 + (j+1)/(i+1)) = F(1 + (i-1)) = f_j(i-1) \). For indices \( i \) that do not satisfy \((i+1)^2 > i+j+2\) we are free to assign any appropriate value to \( e_{j+1}(i) \).

The communications along channels \( e_j \) and \( f_j, j \geq 1 \), can now be implemented by

\[
\begin{align*}
e_1(i) &= f_0(0) \quad &\text{(4)} \\
f_1(i) &= f_0(i) \quad &\text{(5)} \\
e_{j+1}(i) &= \begin{cases} e_j(i) & \text{if } -(i+1 \mid j+1) \lor i = 0 \\ e_j(i-1) & \text{if } 0 < i^2 \leq i+j \\ \end{cases} \quad &\text{(6)} \\
f_{j+1}(i) &= f_j(i) \quad &\text{(7)}
\end{align*}
\]

Recapitulating, we have introduced a number of channels for which we have derived relations that express the dependencies of the individual communications along these channels. These relations give rise to a partial order on the communications along the channels. We now turn our attention to finding a communication behavior for the cells that is consistent with this partial order.

Given relations (0) through (7) we are able to express the requirements for the communication behavior of the cells. We turn our attention to cell \( j (j \geq 1) \). For the sake of convenience, we drop the indices of the channel names and denote channels \( b_j, b_{j+1}, e_j, e_{j+1}, f_j, \) and \( f_{j+1} \) by \( b, \bar{b}, e, \bar{e}, f, \) and \( \bar{f} \), respectively.

Relations (2) and (3) give rise to a partial order on the communications along \( b, \bar{b}, e, f \) (on account of symmetry we temporarily do not consider channels \( g, \bar{g}, h, \) and \( \bar{h} \)). A communication behavior that is consistent with this partial order is

\[
e, f, b; (\bar{b}, e, f ; b)^* \quad &\text{(8)}
\]

Notice that \( e, f, b; (\bar{b}, e, f ; b)^* \) is, among other possibilities, also an appropriate choice. This communication behavior, however, requires extra buffering of three values. Since we aim at minimal buffering we prefer communication behavior (8).

Relation (6) gives rise to

\[
e; \bar{e}; (e, f ; \bar{e})^* \quad &\text{(9)}
\]

And, finally, from relation (7) we infer

\[
(f ; \bar{f})^* \quad &\text{(10)}
\]

These relations can be combined into the following (overall) communication behavior, \( CB \), of cell \( j \) (including channels \( g, \bar{g}, h, \) and \( \bar{h} \))

\[
e, f, g, h; (b, \bar{e}, f, \bar{g}, \bar{h}; \bar{b}, e, f, g, h)^* \quad &\text{(11)}
\]

Notice that the inputs along \( f \) occur earlier in (11) than in (9). Hence, we introduced extra buffering. Also notice the alternation between input actions and output actions.
1 DIRICHLET CONVOLUTION

\[ \text{CB}[\{b,e,f,g,h\} = (e,f,g,h ; b) \]

and

\[ \text{CB}[\{\bar{b},e,f,g,h\} = (e,f,g,h ; \bar{b}) \]

match, we conclude that the computation we derive does not suffer from deadlock (cf. [6]).

The reader is invited to verify that

\[ f,g ; (b,e,f,g,h ; b,f,g) \]

is a possible communication behavior for cell 0.

From relations (0), (1), (4), (5), and (12) we easily derive a program for cell 0:

\[
\begin{align*}
\text{var } & v_f, v_f^0, v_g, v_g^0, v_b : \text{int}; \\
& f? v_f, g? v_g^0 \\
& b!(v_f^0 * v_g^0), e! v_f^0, f! v_f^0, g! v_g^0, h! v_g^0 \\
& (b? v_b, f? v_f, g? v_g) \\
& b!(v_b + v_f * v_g^0 + v_f^0 * v_g), e! v_f^0, f! v_f, g! v_g, h! v_g^0 \\
\end{align*}
\]

And from relations (2), (3), (6), (7), and (11) we derive the following program for cell j:

\[
\begin{align*}
\text{var } & v_e, v_e^0, v_f, v_ff, v_g, v_gg, v_h, v_hh, v_b : \text{int}; \\
& p, q, r, i : \text{int; } \\
& e? v_e^0, f? v_ff, g? v_gg, h? v_hh \\
& b!, e! v_e, f! v_ff, g! v_gg, h! v_hh, i := 0 \\
& (b? v_b, e? v_e, f? v_ff, g? v_gg, h? v_hh) \\
& ; \text{if } (i + 2)^2 < i + j + 2 \lor -(i + 2 \mid j) \rightarrow r := 0 \\
& \quad (i + 2)^2 = i + j + 2 \rightarrow r := v_f * v_g \\
& \quad (i + 2)^2 > i + j + 2 \land (i + 2 \mid j) \rightarrow r := v_f * v_h + v_e * v_g \\
& \quad \text{if } \neg(i + 2 \mid j + 1) \rightarrow p, q := v_e, v_h \\
& \quad (i + 2 \mid j + 1) \land (i + 1)^2 > i + j + 1 \rightarrow p, q := v_e, v_hh \\
& \quad (i + 2 \mid j + 1) \land (i + 1)^2 \leq i + j + 1 \rightarrow p, q := v_f, v_gg \\
& \quad \text{if } b!(v_b + r), e! p, f! v_f, g! v_g, h! q \\
& \quad ; v_e, v_ff, v_gg, v_hh, i := v_e, v_f, v_g, v_h, i + 1 \\
\end{align*}
\]

The above program does not meet the 'modularity constraint' of [3], i.e. j occurs in the program text and as a consequence the operation of a cell depends on the location of that cell in the network. This problem can be eliminated by introducing additional input channels for each cell (this technique has also been applied in [5]). By applying this technique it is possible to implement the evaluation of the guards efficiently. Without going into further detail, we
suggest to introduce three additional input channels $u_j$, $v_j$, and $w_j$, which are specified as follows

\[
\begin{align*}
    u_j(i) &= (i + 1)^2 - (i + j + 1) \\
    v_j(i) &= j \mod (i + 1) \\
    w_j(i) &= i
\end{align*}
\]

for $i \geq 1$.

For example,

\[
(i + 2)^2 < i + j + 2 \lor -(i + 2 | j)
\]

can now be replaced by

\[
u_j(i + 1) < 0 \lor v_j(i + 1) \neq 0
\]

For the sake of completeness, the transformed program texts read

```c
[ var vfo, vf, vg0, vg, vb, vu, vv, vw : int;  
  f? vfo, g? vg0  
  ; vu, vv, vw := -1, 0, 0  
  ; b!(vfo * vg0), e!vfo, f!vfo, g!vg0, h!vg0, u!vu, v!vv, w!vw  
  ; (b?vb, f?vf, g?vg  
  ; vu, vv, vw := vu + 2 * vv + 2, 1, vw + 1  
  ; b!(vb + vf * vg0 + vfo * vg), e!vfo, f!vf, g!vg, h!vg0, u!vu, v!vv, w!vw )*
]
```

and

```c
[ var ve, vee, vf, vff, vg, vgg, vh, vhh, vb, vu, vv, vuu, vv, vnn, vw : int;  
  p, q, r : int;  
  ; b!0, e!vee, f!vff, g!vgg, h!vhh, u!(vuu - 1), b!0, w!vw  
  ; if vu \neq vw \rightarrow vnn := vu + 1 \land vu = vw \rightarrow vnn := 0 fi  
  ; if vu < 0 \lor vu \neq 0 \rightarrow r := 0  
   \land vu = 0 \rightarrow r := vf \star vg  
   \land vu > 0 \land vu = 0 \rightarrow r := vf \star vh + ve \star vg  
  fi  
  , if vnn \neq 0 \rightarrow p, q := ve, vh  
  \land vnn = 0 \land vuu > 0 \rightarrow p, q := vee, vhh  
  \land vnn = 0 \land vuu \geq 0 \rightarrow p, q := vff, vgg  
  fi  
  ; b!(vb + r), e!p, f!vf, g!vg, h!q, u!(vu - 1), v!vnn, w!vw  
  ; vee, vff, vgg, vhh, vuu := ve, vf, vg, vh, vu )*
]
```
We are now done with the construction of our program and conclude this section with a short complexity analysis.

The response time of the program (consider the original program, not the transformed program) is analysed by introducing sequence functions $\sigma_j$ for each cell $j$. For a channel $a$ and natural $i$, $\sigma_j(a,i)$ denotes the time slot in which the $i$-th communication along channel $a$ of cell $j$ can be scheduled. From the communication behavior of the cells, (11) and (12), the following possible sequence function can be inferred (without loss of generality we only consider channels $f, \bar{f}, b, \text{and } \bar{b}$)

$$
\begin{align*}
\sigma_j(f,i) &= 2*i + j \\
\sigma_j(\bar{f},i) &= 2*i + j + 1 \\
\sigma_j(b,i) &= 2*i + j + 1 \\
\sigma_j(\bar{b},i) &= 2*i + j + 2
\end{align*}
$$

For cell $0$ we have $\sigma_0(b,i) = 2*i + 1$. Hence, the computation we derived has constant response time. In the same time slot in which $b_0(i)$ is produced by cell $0$ cell $(2*i + 1)$ receives $f_{2*i+1}(0)$. Thus, computing $(F*G)(n)$, for $1 \leq n \leq N$, involves $\mathcal{O}(N)$ cells and $\mathcal{O}(N)$ time. A sequential solution for computing $(F*G)(n)$, for $1 \leq n \leq N$, has time complexity at least $\mathcal{O}(N \log N)$.

2 Inverse Convolution Problem

In this section we present a parallel program for the inverse convolution problem. It turns out that this parallel program is identical to the parallel program for Dirichlet Convolution, except for the design of cell 0.

The inverse convolution problem is stated as follows: given two arithmetical functions, $G$ and $H$, one has to determine (arithmetical) function $F$ such that $F*G = H$, i.e.

$$H(n) = (S p, q : p * q = n \land 1 \leq p \land 1 \leq q : F(p) * G(q))$$

for $n \geq 1$. Assume $G(1) \neq 0$.

The computation we derive consists of a linear network of cells where cell 0 is fed with the two given arithmetical functions along two input channels, $g_0$ and $h_0$:

$$
\begin{align*}
g_0(i) &= G(i+1) \\
h_0(i) &= H(i+1)
\end{align*}
$$

for $i \geq 0$.

Communication with the environment is established by means of output channel $b_0$, which satisfies

$$b_0(i) = F(i+1)$$

for $i \geq 0$ and $F$ satisfying $F*G = H$.

Since $F$ is defined implicitly we derive relations for $F(n)$ and, next, extract $F(n)$ from these.

From $H(1) = F(1) * G(1)$, we readily conclude

$$b_0(0)$$
2 INVERSE CONVOLUTION PROBLEM

\[
= \{ \text{def. } b_0 \} \\
F(1)
\]

\[
= \{ \text{relation above; } G(1) \neq 0 \} \\
H(1)/G(1)
\]

\[
= \{ \text{def. } g_0 \text{ and } h_0 \} \\
h_0(0)/g_0(0)
\]

For \( n \geq 1 \), we have

\[
H(n + 1) = \{ F * G = H \} \\
(\sum p,q : p * q = n + 1 \land (\sqrt{n + 1} \leq p \lor \sqrt{n + 1} \leq q) : F(p) * G(q))
\]

\[
= \{ \text{domain split; } 1 < \sqrt{n + 1} \} \\
F(1) * G(n + 1) + F(n + 1) * G(1)
\]

\[
+ (\sum p,q : p * q = n + 1 \land (\sqrt{n + 1} \leq p \lor \sqrt{n + 1} \leq q \leq n) : F(p) * G(q))
\]

Since \( G(1) \neq 0 \), we conclude that function \( F \) is unique.

Now, recall the definition of \( Q(m,n) \) from the previous section. \( Q(m,n) \) has been defined in the context of arithmetical functions \( F \) and \( G \). Therefore, it is possible to substitute \( Q(n,n + 1) \) for the quantified summation in the derivation above, giving

\[
H(n + 1) = F(1) * G(n + 1) + F(n + 1) * G(1) + Q(n,n + 1)
\]

Cell 0 should have at its disposal the value of \( Q(n,n + 1) \) for each \( n \geq 1 \). For this purpose we can use the cells with \( j \geq 1 \) that already have been implemented in the previous section. Then \( b_1(i) = Q(i + 1,i + 2) \) for \( i \geq 0 \), provided that cell 1 is supplied with the proper values. For \( i \geq 0 \) we derive

\[
\begin{align*}
&b_0(i + 1) \\
&= \{ \text{def. } b_0 \} \\
&\quad F(i + 2)
\end{align*}
\]

\[
= \{ \text{above relation for } H(n + 1); G(1) \neq 0 \} \\
(H(i + 2) - F(1) * G(i + 2) - Q(i + 1,i + 2))/G(1)
\]

\[
= \{ \text{def. } g_0, h_0, b_0, \text{ and } b_1 \} \\
(h_0(i + 1) - b_0(0) * g_0(i + 1) - b_1(i))/g_0(0)
\]

Summarizing:

\[
\begin{align*}
b_0(0) &= h_0(0)/g_0(0) \\
b_0(i + 1) &= (h_0(i + 1) - b_0(0) * g_0(i + 1) - b_1(i))/g_0(0)
\end{align*}
\]

A possible communication behavior for cell 0 is (cf. (12))

\[
g, h ; (b, e, f, g, h ; b, g, h)'
\]
3 THE MÖBIUS FUNCTION

The corresponding program for cell 0 reads

```c
[ var vf0, vf, vg0, vg, vb, vh : int;
  g?vg0, h?vh
  ; vf0 := vh/vg0
  ; b?vf0, e!vf0, f!vf0, g!vg0, h!vg0
  ; (b?vb, g?vg, h?vh
  ; vf := (vh - vf0 * vg - vb)/vg0
  ; b!vf, e!vf0, f!vf, g!vg, h!vg0
]
```

3 The Möbius Function

The Möbius function \( \mu \) is the arithmetical function defined by

\[
\mu(n) = \begin{cases} 
0 & \text{if } (\exists m : m > 1 : m^2 | n) \\
(-1)^{\tau(n)} & \text{otherwise}
\end{cases}
\]

for \( n \geq 1 \), where \( \tau(n) \) denotes the number of prime divisors of \( n \).

It is well-known that the Möbius function is an instance of the inverse convolution problem, viz.

\[
\mu * E = U
\]

where \( E \) is the all-one function, and \( U \) is defined by \( U(1) = 1 \), and \( U(n) = 0 \) for all \( n > 1 \).

A parallel program that computes the Möbius function can be obtained from the program for the (general) inverse convolution problem by feeding cell 0 with input streams \( g \) and \( h \) that satisfy \( g(i) = E(i + 1) \) and \( h(i) = U(i + 1) \) for \( i \geq 0 \). By exploiting knowledge about functions \( E \) and \( H \) it is possible, however, to eliminate a number of communication actions from the program texts of the cells. By doing so, the input channels of cell 0 can be omitted which results in a parallel program that only produces output.

After elimination of redundant statements we obtain the following program texts. For cell 0 we get

```c
[ var vb : int;
  b!1, e!1, f!1
  ; (b?vb
  ; b!(-vb - 1), e!1, f!(-vb - 1)
]
```

and for cell \( j \) \( (j \geq 1) \)
Our program for generating the Möbius function differs from the program presented in [5]. This is mainly caused by the fact that in [5] there was no need for a 'symmetric solution'. Such a solution even would not have been obvious.

4 Conclusion Remarks

We have derived parallel programs for Dirichlet Convolution and for the inverse convolution problem in a calculational, rather straightforward manner. A key issue in the derivation was the decision to maintain the symmetry of the problem specification in the generalized expression $Q(m, n)$. It is our experience that destroying symmetry in the derivation of parallel programs often yields inefficient solutions. In fact, this observation has also been made in [0, section 3]. Another important step in the derivation was the fact that we did not specify the additional input channels $e_j$ and $h_j$ for all natural $i$. In this way we made it possible to apply the second property that we derived for the div-operator.

We believe that our derivation is much clearer than the program derivations given in [3] and [0], which are, in a sense, based on similar but less explicit observations as our solution is based on. In [3], a rather intricate routing scheme is given for the routing of 'F-coefficients' and 'G-coefficients', which can be compared to the input channels $e_j$ and $h_j$ in our solution. We, however, refrained from giving an operational explanation for the behavior of the values communicated along channels $e_j$ and $h_j$: such an explanation would only complicate the reasoning about our program. In [0], 'domain contraction' has been applied in order to obtain an efficient (symmetric) solution. This technique seems to be a little magical and hard to understand if one is not familiar with the method.

Starting from a parallel program for Dirichlet Convolution it turned out to be very simple to derive a parallel program for the inverse convolution problem: both programs are identical except for the design of cell 0. We have already come across this phenomenon in the design of systolic arrays for polynomial multiplication and division (cf. [4]).

Finally, we have presented a parallel program for computing the Möbius function. Our pro-
gram differs from the program presented in [5], which is mainly caused by the fact that in [5] there was no need for a 'symmetric solution'. Such a solution even would not have been obvious.
