Abstract

In this paper we shall meet the application of Scott domains to nominalisation and explain its problem of predication. We claim that it is not possible to find a solution to such a problem within semantic domains without logic. Frege structures are more conclusive than a solution to domain equations and can be used as models for nominalisation. Hence we develop a type theory based on Frege structures and use it as a theory of nominalisation.

Keywords: Frege structures, Nominalisation, Logic and Type freeness.
1 Frege structures, a formal introduction

Having in part I informally introduced Frege structures, I shall here fill in all the technical details and show that Frege structures exist.

Consider $F_0, F_1, \ldots$, a family $F$ of collections where $F_0$ is a collection of objects, and $(\forall n > 0)[F_n$ is a collection of $n$-ary functions from $F_n^0$ to $F_0]$.

Definition 1.1 (An explicitly closed family) A family $F$ as above is explicitly closed iff:

1. For every expression $e[x_1, \ldots, x_n]$ of the metalanguage built up in the usual way from variables ranging over $F_0$ and constants ranging over $\bigcup_n F_n$, the $n$-place function denoted by $< e[x_1, \ldots, x_n]/x_1, \ldots, x_n >$ is in $F_n$. More formally, $F$ is explicitly closed iff 1, 2 and 3 below hold:

1. Closure under constant functions: For each $a$ in $F_0$, the function $f_a$ is in $F_1$, where $f_a(x) = a$.

2. Closure under composition: For each $f$ in $F_m$, for each $g_1, \ldots, g_m$ in $F_k$, $f(g_1, \ldots, g_m)$ is in $F_k$ where $(f(g_1, \ldots, g_m))(x_1, \ldots, x_k) = f(g_1(x_1, \ldots, x_k), \ldots, g_m(x_1, \ldots, x_k))$.

3. Closure under projection: For each $n, i \geq 1$, $P_i^n$ is in $F_n$ where $P_i^n(a_1, \ldots, a_n) = a_i$ for each $a_i$ in $F_0$ and, $1 \leq i \leq n$.

For example, if $f$ and $g$ are unary functions of $F$ and $h$ is a binary function of $F$, then $< f \circ g(h(x_1, x_2))/x_1, x_2 >$ is a 2-ary function (i.e. in $F_2$).

In what follows, we assume such a closed family and call it $F$.

Definition 1.2 ($F$-functional) A function $D : F_{n_1} \times \ldots \times F_{n_k} \rightarrow F_0$ is an $F$-functional with respect to the explicitly closed family $F$, iff: $(\forall m \geq 0)(\forall f_1 \text{ in } F_{m+1}) \ldots (\forall f_k \text{ in } F_{m+n_k})$ $< D(< f_1(y, x_1)/x_1 >, \ldots, < f_k(y, x_k)/x_k >)/y >$ is in $F_m$ where $y$ is a list of $m$-variables and $x_i$ is a list of $n_i$ variables, for $i = 1, \ldots, k$.

Note that if $f_1, \ldots, f_k$ are 1-place functions and $D : F_1 \times \ldots \times F_1 \rightarrow F_0$ then $D(f_1, \ldots, f_k)$ is in $F_0$. What is the intuitive meaning of $F$-functionals? We know that an $F$-functional is a functional, so that it operates on functions. But once we include functionals in the structure, we need to ensure that any expression which contains functionals should actually be in the structure. Assume for the sake of argument that $D : F_{n_1} \times \ldots \times F_{n_k} \rightarrow F_0$ is an $F$-functional. Assume also that for some $m \geq 0$, $f_i$ is in $F_{m+n_i}$ for $i = 1, \ldots, k$. We know that according to the explicit closure, if $y$ is a list of $m$-variables, then $< f_i(y, x_i)/x_i >$ is an element of $F_{n_i}$ for each $i$. Therefore it makes sense to talk of the expression $D(< f_1(y, x_1)/x_1 >, \ldots, < f_k(y, x_k)/x_k >)$. This expression however is open in $y$ and if we abstract over $y$ in this expression are we going to obtain an element of $F_m$? Nothing so far in the structure ensures that this is the case, and we must therefore impose the constraint that these functionals should have such a property. A functional which has this property is called an $F$-functional and now if $D$ is an $F$-functional then $< D(< f_1(y, x_1)/x_1 >, \ldots, < f_k(y, x_k)/x_k >)/y >$ is in $F_m$. Hence we extend the definition of explicit closure to the following:

Definition 1.3 (A super explicitly closed family) Taking a family as above, we say that this family is super explicitly closed iff for every expression $e[\xi_1, \ldots, \xi_m]$ of the metalanguage,
built up in the usual way from variables ranging over $\cup_n F_n$ and constants ranging over $\cup_n F_n$ and over $F$-functionals, the $m$-place function denoted by $< e[\xi_1, \ldots, \xi_m]/x_1, \ldots, x_m >$ is an $F$-functional.

This notion of explicit closure is going to provide us with the full comprehension principle we have been promising.

**Theorem 1.4** Any explicitly closed family which has variables for functions and objects, constants for objects, functions and $F$-functionals, is a super explicitly closed family. (The proof is by an easy induction.)

**Example 1.5** As an example of an explicitly closed family, consider $P_\omega$ as described previously. Define $F_0$ to be the set of all subsets of $\omega$ (i.e. $P_\omega$). Define, for each $n \geq 0, F_n$ to be the set of all continuous functions from $F^n_0 \to F_0$. Using Part I, it can be easily seen that the constant functions, the projection functions, etc are continuous. It can also be seen that continuity is closed under composition and that any combination $e[x_1, \ldots, x_n]$ of variables for objects and constants for both functions and objects results in the function denoted by $< e[x_1, \ldots, x_n]/x_1, \ldots, x_n >$ being an element of $F_n$. Therefore the family $(F_n)_n$ just obtained from $P_\omega$ (call it $FE$), is an explicitly closed family. Furthermore, $FE$ is super explicitly closed as it can be proven not only that $< e[x_1, \ldots, x_n]/x_1, \ldots, x_n >$ denotes a continuous function but also that for any expression $e[\xi_1, \ldots, \xi_n]$ built in the usual way out of variables ranging over $\cup_n F_n$ and constants ranging over both $\cup_n F_n$ and $F$-functionals, $< e[\xi_1, \ldots, \xi_n]/\xi_1, \ldots, \xi_n >$ denotes a continuous function.

So far, we have only explicit closure on our structure. But that is not enough to give a logic on the structure. In what follows, we see how to obtain such a logic.

Assume an explicitly closed family $F$ and a list of logical constants which are the following $F$-functionals:

- $\neg : F_0 \to F_0$
- $\forall, \land, \to, \exists : F_0 \times F_0 \to F_0$
- $\forall, \exists : F_1 \to F_0$

**Definition 1.6** (Logical system) A logical system on a super explicitly closed family $F$, relative to a set of logical constants as above, is $< \text{PROP}, \text{TRUTH} >$ the set of two collections of objects such that $\text{TRUTH} \subseteq \text{PROP}$. These two collections are closed under an adopted logical schemata for each logical constant. The logical schemata corresponds to the external logic and tells us, for each logical constant from the list, how to build new propositions out of other ones using the logical constant. It also gives the conditions of truth for the resulting proposition.

**THE LOGICAL SCHEMATICA**

- **NEGATION** If $a$ is in $\text{PROP}$ then $\neg a$ is in $\text{PROP}$ and $\neg a$ is in $\text{TRUTH}$ iff $a$ is not in $\text{TRUTH}$.
- **CONJUNCTION** If $a, b$ are in $\text{PROP}$ then $(a \land b)$ is in $\text{PROP}$ and $(a \land b)$ is in $\text{TRUTH}$ iff $a$ is in $\text{TRUTH}$ and $b$ is in $\text{TRUTH}$.
- **DISJUNCTION** If $a, b$ are in $\text{PROP}$ then $(a \lor b)$ is in $\text{PROP}$ and $(a \lor b)$ is in $\text{TRUTH}$ iff $a$ is in $\text{TRUTH}$ or $b$ is in $\text{TRUTH}$.
• **IMPLICATION** If \( a \) is in \( \text{PROP} \) and \( b \) is in \( \text{PROP} \) provided that \( a \) is in \( \text{TRUTH} \) then \((a \rightarrow b)\) is in \( \text{PROP} \) and \((a \rightarrow b)\) is in \( \text{TRUTH} \) iff \( a \) is in \( \text{TRUTH} \) implies \( b \) is in \( \text{TRUTH} \).

• **UNIVERSAL QUANTIFICATION** If \( f \) is a propositional function in \( F_1 \) then \( \forall f \) is in \( \text{PROP} \) and \( \forall f \) is in \( \text{TRUTH} \) iff \( f(a) \) is in \( \text{TRUTH} \) for all objects \( a \).

• **EXISTENTIAL QUANTIFICATION** If \( f \) is a propositional function in \( F_1 \) then \( \exists f \) is in \( \text{PROP} \) and \( \exists f \) is in \( \text{TRUTH} \) iff \( f(a) \) is in \( \text{TRUTH} \) for some object \( a \).

• **EQUALITY** If \( a, b \) are objects then \((a = b)\) is in \( \text{PROP} \) and \((a = b)\) is in \( \text{TRUTH} \) iff \( a = b \).

• **BI-IMPLICATION** If \( a, b \) are in \( \text{PROP} \) then \((a \leftrightarrow b)\) is in \( \text{PROP} \) and \((a \leftrightarrow b)\) is in \( \text{TRUTH} \) iff \( a \leftrightarrow b \).

From now on, we shall use \( a \) is true for \( a \) is in \( \text{TRUTH} \), \( a \) is a proposition for \( a \) is in \( \text{PROP} \) and \( a \) is a set for \( a \) is in \( \text{SET} \). In short, a logical system builds a logic on our structure. But something is still missing: even, though we built the logical system on the top of an explicitly closed structure, where functional abstraction \(< xe[1,\ldots,x_n]/x_1,\ldots,x_n>\) and application \(f(x)\) do exist, we still need a way of turning functions into objects (via \( \lambda \)) and of applying such objects to other objects (via \( \text{app} \)) so that \( \text{app}(\lambda f, x) = f(x) \). We do not want to gain logic yet lose the bijection between objects and functions. Therefore, our structure must have more in it. The next definition will tell us what.

**Definition 1.7** (\( \lambda \)-system) A \( \lambda \)-system on an explicitly closed family \( F \) is a pair of functionals \(< \lambda, \text{app} > \) such that: \( \lambda : F_1 \rightarrow F_0 \) and \( \text{app} : F_0 \times F_0 \rightarrow F_0 \) satisfy: \( \text{app}(\lambda x f(x), a) = f(a) \), for each \( f \) in \( F_1 \) and \( a \) in \( F_0 \).

**Example 1.8** If we take the system \( FE \) of Example 1.5, and if we define \( \lambda : F_1 \rightarrow F_0 \) as \( \lambda f = \{(n_m) : m \text{ is in } f(e_n)\} \) where we take \( (n_m) \) to be \( 1/2(n+m)(n+m+1) + m \) and define \( \text{app} : F_0 \times F_0 \rightarrow F_0 \) as \( \text{app}(a, b) = \{m : e_n \subseteq a \text{ for some } n,(n_m) \text{ is in } a\} \) then \( (\lambda, \text{app}) \) forms a \( \lambda \)-system for \( FE \).

Proof: \( \text{app}(\lambda f, a) = \{m : e_n \subseteq a \text{ for some } n \text{ and } (n_m) \text{ is in } f(e_n)\} = \{m \in f(e_n) : e_n \subseteq a \} = f(a) \text{ by continuity.} \)

Therefore \( (\lambda, \text{app}) \) is a \( \lambda \)-system for \( FE \). Actually, \( FE \) contains \( \lambda \) and \( \text{app} \) and so it is a \( \lambda \)-structure, but we leave this to the next definition.

---

1 Recall that \( \forall, \exists \) and \( \lambda \) are functions from \( F_1 \) to \( F_0 \) and hence \( f \) does not necessarily contain any free variables.

2 For example, \(< x/z >\) is the identity function and contains no free variables, \( \lambda < x/z > \) can be written as \( \lambda x.x \). The same holds for \( \forall < x/z > \) and \( \exists < x/z > \). This might be confusing, as it might be asked if \(< x/z >\) has no free variables, then what does \( \lambda < x/z > \) mean? Despite the fact that \(< x/z >\) has no free variables (let us denote \( < x/z > \) by \( I \)), it is still an element of \( F_1 \). I.e., it is still a function and we need to make it an object by nominalizing it. Therefore we turn it into an element of \( F_0 \) by using \( \lambda \). Now \( \lambda f \) is in \( F_0 \) and \( \text{app}(\lambda f, a) = I(a) = a \). In fact, \( \lambda \) does not abstract on free variables, it is \(< f >\) which does so. \( \lambda \) just turns a function into an object preserving the comprehension axiom: \( \text{app}(\lambda f, x) = f(x) \). When we say \( \lambda x.x \), we don't mean that \( \lambda \) abstracts over \( x \) in \( x \), rather we mean that we first abstract via \( < f >\) obtaining \( < x/z >\) and then we look for the nominal of \( < x/z >\).

3 Note the two equal signs, = and =. The first is a functional from \( F_0 \times F_0 \) to \( F_0 \) such that \( a = b \) is always a proposition and \( a = b \) is true iff we can prove from the rules of \( \lambda \)-calculus with logic that we are formulating that \( a = b \). For example, we know from above that \( \text{app}(\lambda f, x) = f(x) \), hence the proposition \( \text{app}(\lambda f, x) = f(x) \) is true.
**Definition 1.9** (λ-structure) A λ-structure is an explicitly closed family $F$ which has a λ-system.

Note that the λ-structure contains λ and app and that it is an explicitly closed family.

**Example 1.10** Now take the λ-system $FE$ given in Example 1.8. $FE$ is also a λ-structure having $(\lambda, \text{app})$ as λ-system, because both λ and app are in $FE$, as $FE$ is explicitly closed.

**Definition 1.11** (Frege structures) A Frege structure is a logical system relative to a list of logical constants on an explicitly closed family $F$, together with a λ-system.

**Example 1.12** As an example of a Frege structure, take the λ-structure $FE$ given in Example 1.10 and which has a λ-system $(\lambda, \text{app})$. Aczel (in [Aczel 1985]) showed that each λ-structure can be extended to a Frege structure. Therefore we now have an example of a Frege structure.

Let us sketch the proof of how our particular λ-structure $FE$ can be extended to a Frege structure. This will make the reader understand the notion of Frege structure, and get him used to working with it. Before proceeding, however, we must define two missing notions: that of an independent family of F-functionals and of a primitive F-functional.

**Definition 1.13** We say that a family of F-functionals is independent iff for any two F-functionals in the family, the range of values of those F-functionals are disjoint.

This implies that if $F$ and $G$ belong to an independent family of F-functionals, then for any $\bar{f}$ and $\bar{g}$ such that $F(\bar{f}) = G(\bar{g})$, we should definitely have $F = G$. From independence only we cannot conclude that $\bar{f} = \bar{g}$. For this we need primitivity and this is the next notion we define.

**Definition 1.14** We say that an F-functional $F : F_{n_1} \times \ldots \times F_{n_k} \rightarrow F_0$ is primitive iff there exists a projection $P_i$ in $F_{n_{i+1}}$ for each $1 \leq i \leq k$ such that $P_i(F(\bar{f}), \bar{a}) = f_i(\bar{a})$ where $\bar{f} = f_1, \ldots, f_k$ is in $F_{n_1} \times \ldots \times F_{n_k}$ and $\bar{a}$ is in $F_0$.

The aim of primitive F-functionals is similar to injectivity; if we have $F(\bar{f}) = F(\bar{g})$ then we should be able to deduce $\bar{f} = \bar{g}$. It can be easily checked from the definition of F-primitiveness that this is the case.

The proof that we can extend any λ-structure into a Frege structure is based on two theorems. The first is one which asserts the existence of an independent family of primitive F-functionals on the λ-structure, which include the logical constants, $\land, \lor$ etc. It simply states that:

**Theorem 1.15** If for each natural number $m$ we let $(v_{m_1}, \ldots, v_{m_k})$ be a finite sequence of natural numbers, then there is an independent family of primitive F-functionals:

$$F_m : F_{v_{m_1}} \times \ldots \times F_{v_{m_k}} \rightarrow F_0, \text{ for } m = 0, 1, 2, \ldots$$

The second is the well known fixed point theorem which applies to monotonic operators and helps us to find the logical schema of these logical constants. This theorem simply states the following:
Theorem 1.16 If $A$ is a partially ordered collection of objects such that every chain in $A$ has a least upper bound then any monotonic operator $Y$ from $A$ to $A$ has a fixed point. That is, $(\exists a \in A)[Y(a) = a]$.

Let us apply those two theorems to our $FE$ and obtain out of it a Frege structure. Up to here, we know that the $\lambda$-structure $FE$ exists and Theorem 1.15 enables us to find all the logical constants needed. What remains to turn it into a Frege structure is to find a logical system for the logical constants. This is the task of Theorem 1.16. The idea is to associate with each logical constant two predicates which will ultimately (after we get to the fixed point) give all the propositions obtained from the logical constant and all the truths respectively. The construction is well known mathematically and is similar to the one followed by Kripke in [Kripke 1963]. Now consider our $\lambda$-structure $FE$. We can be sure from Theorem 1.15 that we have a list of $F$-functionals which includes:

- $\neg : F_0 \rightarrow F_0$
- $\lor, \land, \rightarrow, =, \neq : F_0 \times F_0 \rightarrow F_0$
- $\forall, \exists : F_1 \rightarrow F_0$

But we still need to make sure that they satisfy the closure properties we want to impose on them. I shall here try to make the construction a little easier than that described by Aczel (in [Aczel 1985]). To construct a logical schema for each constant, i.e. to define the whole logical system, we follow Aczel's intended construction but will carry an example with us at all times. The logical system is defined inductively. As the basis of the induction, we start with a pair $\chi_0 = (\chi_{op}, \chi_{ot})$ such that $\chi_{ot} \subseteq \chi_{op}$. Intuitively, $\chi_{op}$ is the set of propositions at stage 0 and $\chi_{ot}$ is the set of truths at stage 0.

**Example 1.17** Let $\chi_0 = (\chi_{op}, \chi_{ot}) = (\{0, 1\}, \{1\})$. Note that both $\{0, 1\}$ and $\{1\}$ are in $P_w$.

Before proceeding to the induction step, we must define a couple of auxiliary predicates which ensure that the logical constants map their arguments into appropriate values. That is, for each logical constant $F$, there is one predicate $\Phi_F$ which tests whether a particular tuple of arguments has the correct status of propositionhood, and a second predicate $\Psi_F$ which states the conditions under which the tuple will be mapped into $\text{TRUTH}$ by $F$. To see why we need this, recall the logical schema for negation that we presented under $\text{NEGATION}$ above:

- (1) If $a$ is in $\text{PROP}$ then $\neg a$ is in $\text{PROP}$, and $\neg a$ is in $\text{TRUTH}$ iff $a$ is not in $\text{TRUTH}$.

This is an instance of a general logical schema for those functionals $F$ in a Frege structure which correspond to truth-functional connectives:

- (2) If $\bar{f}$ is in $F_{n_1} \times \ldots \times F_{n_k}$ and $C'(F, \bar{f})$, then $F(\bar{f})$ is in $\text{PROP}$; and $F(\bar{f})$ is in $\text{TRUTH}$ iff $C(F, \bar{f})$, where $C$ expresses $F$'s truth conditions and $C'$ expresses $F$'s propositionhood.

Now it is $\Phi_F$ which tests that the arguments $\bar{f}$ are in $\text{PROP}$, while $\Psi_F$ does the work of $C$ in (2).

**Example 1.18** $\Phi_-$ and $\Psi_-$ take arguments in $(\cup X_i) \times F_0$ and

- $\Phi_-(x_0, x)$ is: $x$ is in $\chi_{op}$
- $\Psi_-(x_0, x)$ is: $x$ is in not $\chi_{ot}$

Thus, $\Phi_-(x_0, x)$ is true of the set $\chi_{op} = \{0, 1\}$, and $\Psi_-(x_0, x)$ is true of all elements in $F_0 \setminus \chi_{ot}$, i.e. everything except the element $i$. 

6
In order to carry out the induction step of the construction, we introduce a principle which determines how the propositions and truths at stage $i + 1$ are built from the propositions and truths at stage $i$. The principle has two parts as follows:

**Principle 1.19** $X_{i+1p}$ is the collection of those $F(\bar{f})$ where $F$ is a logical constant and $\Phi_F(X_i, \bar{f})$.

**Principle 1.20** $X_{i+1t}$ is the collection of those $F(\bar{f})$ where $F$ is a logical constant and both $\Psi_F(X_i, \bar{f})$ and $\Phi_F(X_i, \bar{f})$.

In other words, given the pair $(X_{ip}, X_{it})$, we construct $(X_{i+1p}, X_{i+1t})$ in the following way:

first, $X_{i+1p}$ has to contain all and only those elements $F(\bar{f})$ such that $\bar{f}$ belongs to the propositions at stage $i$, i.e. it is in $X_{ip}$ according to $\Phi_F(X_i, \bar{f})$; and second, $X_{i+1t}$ must contain all and only those elements $F(\bar{f})$ such that $\bar{f}$ belongs to both the propositions and the truths at stage $i$, i.e. it is in $X_{ip}$ and $X_{it}$ according to $\Phi_F(X_i, \bar{f})$ and $\Psi_F(X_i, \bar{f})$.

Notice that the principle guarantees that $X_{(i+1)t} \not\subseteq X_{(i+1)p}$.

**Example 1.21** We wish to build $X_1 = (X_{1p}, X_{1t})$ from $(X_{0p}, X_{0t}) = (\{0, 1\}, \{1\})$. By Principle 1.19, $X_{1p}$ is the set of objects $\neg x$ such that $\Phi_(\neg x, \bar{f})$, i.e. it is the set $\{\neg 0, \neg 1\}$. By Principle 1.20, $X_{1t}$ is the set of objects $\neg x$ such that $\bar{f}$ belongs to $X_{0p}$ but does not belong to $X_{0t}$. The only thing which satisfies both these conditions is $0$, so $X_{1t} = \{\neg 0\}$.

**Example 1.22** $\Phi_\Lambda$ and $\Psi_\Lambda$ take arguments in $(\bigcup X_i) \times (F_0 \times F_0)$ and

$\Phi_\Lambda(\chi_0, (x, y))$ is: $x$ and $y$ are in $\chi_{0p}$

$\Psi_\Lambda(\chi_0, (x, y))$ is: $x$ and $y$ are in $\chi_{0t}$

Thus, we can supplement the $X_{1p}$ of the previous example with the set of objects $\Lambda(x, y)$ such that $(x, y) \subseteq \chi_{0p} \times \chi_{0p}$, i.e. the set $\{0 \land 0, 0 \land 1, 1 \land 0, \ldots\}$. Similarly, we add to $X_{1t}$ the set of objects $\Lambda(x, y)$ such that $(x, y) \subseteq \chi_{0p} \times \chi_{0t}$, i.e. the set $\{1 \land 1\}$. Note that according to our example, the collection of objects in TRUTH at stage 1 is $\{1 \land 1, \neg 0\}$.

Note also that $\neg 0, 1 \land 1, 1 \forall 0$ are distinct objects, even though they are all in TRUTH and all have the same truth value in Frege's terms. If we wish, we could reconstruct Frege's notion of the True and the False by forming the relevant equivalence classes, but Frege structures give us an intensional ontology. This is justified on the grounds that objects with the same truth value, e.g. $\neg 0$ and $1 \land 1$ are equivalent in truth value but distinct.

We see that the pair is being enlarged at each step starting from the first step where we take $\chi_{0p} = \{0, 1\}$ and $\chi_{0t} = \{1\}$, with the property that for each $i$ we have: $\chi_i \subseteq \chi_{ip}$. Note that we are not imposing the condition that $\chi_{it} \subseteq \chi_{i+1t}$ or $\chi_{ip} \subseteq \chi_{i+1p}$; in fact our construction is monotonic in another sense which we shall see below. The aim is now to keep going up to a certain level $\alpha$ where $\chi_\alpha = (\chi_{\alpha p}, \chi_{\alpha t})$ is a logical system, because it is obvious that $\chi_1$ at the levels we met so far are not logical systems. Take for example $\chi_0$ in our example above based on FE. Then $\chi_0$ is not a logical system, as can be seen by taking the logical schema for $\neg$.

If $a$ is a proposition then $\neg a$ is a proposition such that $\neg a$ is true iff $\neg a$ is not true.

$\chi_0$ is not a logical system because $1$ is in $\chi_{0p}$ (supposed to represent propositions) but $\neg 1$ is not in $\chi_{0p}$. Nor is $\chi_1$ a logical system because $\neg 1$ is in $\chi_{1p}$ but $\neg \neg 1$ is not in $\chi_{1p}$ and so on. To solve this problem, let us consider the fixed point (if it exists) of this construction. It
may be that the fixed point is a logical system and if so, we have succeeded. Before we prove
that the fixed point is a logical system, let us remind ourselves again of the construction. The
construction is built through an operator $Y$ which takes us from level $i$ to level $i+1$ in such a
way that $Y(X_i) = X_{i+1}$, where $X_i = (X_{iP}, X_{iI})$, $X_{i+1} = (X_{i+1P}, X_{i+1I})$, $X_{iP} \subseteq X_{iP}$, $X_{i+1I} \subseteq X_{i+1P}$. Moreover $X_{i+1P}$ and $X_{i+1I}$ are obtained as follows:

For any $F$-functional $F$, $X_{i+1P}$ is the collection of those $F(!)$ where $F$ is a logical constant
and $\Phi_F(X_i, f)$ and $X_{i+1I}$ is the collection of those objects $F(f)$ where $F$ is a logical constant
and both $\Phi_F(X_i, f)$ and $\Psi_F(X_i, f)$. Now we prove that any $\chi$ such that $\chi = Y(\chi)$ is a logical
system. To show that, we have to prove that for each logical constant $F$, the logical schemata
of $F$ holds in $\chi$. Let $F$ be a logical constant whose logical schema is as follows:

- $\Phi_F(X_i, f)$ if $F(!)$ is in $X_{iP}$; and $F(f)$ is in $X_i$ iff $\Psi_F(X_i, f)$.

This implies that the logical schema of $F$ holds in $\chi$. Now we know that if there exists a fixed
point $\chi$ then this $\chi$ is a logical system. Let us find a fixed point.

We define an ordering $\leq$ on $(X_i)$; as follows: $\chi_i \leq \chi_{i+1}$ if

- $\chi_{iP} \subseteq \chi_{i+1P}$, and
- if $x$ is in $\chi_{iP}$, then $x$ is in $\chi_{iI}$ iff $x$ is in $\chi_{i+1I}$.

With this ordering we can show that $Y$ is monotonic. Note that the levels can be any
ordinal even a transfinite one, for if we are at a finite ordinal $i$ we define $Y(X_i) := X_{i+1}$ as
above. If we are at a limit ordinal $j$, we define $Y(X_j) = \bigcup X_i$ for $i < j$. Applying the fixed
point theorem we get a fixed point of $Y$. The reason for this is of course the monotonicity
of the operator $Y$, as we know that the ordering relation $\leq$ is a partial ordering on all those
pairs.

\section{Scott Domains and nominalisation}

The ordering relation on Scott domains makes predication trivial. For, a predicate $P$ is true
of all the objects in the model iff it is true of the bottom element. Both semanticians and
computer scientists however, share an interest in quantification and hence this problem of
predication that faced Turner (in [Turner' 1984]) is a major issue for those interested in the
semantics of either computer or natural languages and who base their work on Scott domains.

The problem can be described as follows: Assume a language which has both objects and
functions and assume that wffs are built out of other ones using $\land, \lor, \forall, \exists, \ldots$ If the model is
a Scott domain $E_\infty$ then there is no problem interpreting anything which is not a quantified sentence, as the interpretations of all such things are continuous functions and hence belong to the model. Let us choose the following interpretation for the quantifiers $\forall$ and $\exists$

$[[\forall x \phi]]_{gut} = \begin{cases} 
1 & \text{if for each } d \in D, [[\phi]]_{g[d/x]} = 1 \\
0 & \text{if for some } d \in D, [[\phi]]_{g[d/x]} = 0 \\
\bot & \text{otherwise}
\end{cases}$

$[[\exists x \phi]]_{gut} = \begin{cases} 
1 & \text{if for some } d \in D, [[\phi]]_{g[d/x]} = 1 \\
0 & \text{if for each } d \in D, [[\phi]]_{g[d/x]} = 0 \\
\bot & \text{otherwise}
\end{cases}$

Then the following is a proof of the continuity of the quantifier clause for $\forall$. Assume by induction that we have $[[\phi]]$ is continuous where $\phi$ does not involve quantifiers. To prove the continuity of $[[\forall x \phi]]$ (i.e. to prove it in $[ASG \rightarrow [S \rightarrow EXT]]$ where $ASG$ is the collection of assignment functions, $S$ is the collection of states consisting of worlds and times and $EXT$ is the extensional domain of values), we prove it continuous separately in each of its arguments, according to a theorem related to semantic domains.

Let us prove the continuity of $[[\forall x \phi]]$ for $g$ in $ASG$. Take an $\omega$-sequence $(g_n)_n$ and prove that: $[[\forall x \phi]]_{\cup g_n} = \cup[[\forall x \phi]]_{g_n}$.

- Assume $[[\forall x \phi]]_{\cup g_n} = 0 \iff$ by definition,

$(\exists d \in D)([[\phi]]_{\cup g_n[d/x]} = 0) \iff$ by induction,

$(\exists d \in D)(\cup[[\phi]]_{g_n[d/x]} = 0) \iff$ by the structure of BOOL,

$(\exists d \in D)(\exists n \in W)([[\phi]]_{g_n[d/x]} = 0) \iff$ by logical laws,

$(\exists n \in W)(\exists d \in D)([[\phi]]_{g_n[d/x]} = 0) \iff$ by definition,

$(\exists n \in W)(\forall x [[\phi]]_{g_n[d/x]} = 0) \iff$ by the structure of Bool,

$\cup[[\forall x \phi]]_{g_n} = 0$

- Assume $[[\forall x \phi]]_{\cup g_n} = 1 \iff$ by definition,

$(\forall d \in D)([[\phi]]_{\cup g_n[d/x]} = 1) \iff$ by induction,

$(\forall d \in D)(\cup[[\phi]]_{g_n[d/x]} = 1) \iff$ by the structure of BOOL,

$(\forall d \in D)(\exists n \in W)([[\phi]]_{g_n[d/x]} = 1) \iff$ $u \subseteq d$ and monotonicity,

$(\exists n \in W)([[\phi]]_{g_n[d/x]} = 1) \iff$ monotonicity,

$(\exists n \in W)(\forall d \in D)([[\phi]]_{g_n[d/x]} = 1) \iff$ by definition,

$(\exists n \in W)(\forall x [[\phi]]_{g_n[d/x]} = 1) \iff$ by the structure of Bool,

$\cup[[\forall x \phi]]_{g_n} = 1$

Therefore $[[\forall x \phi]]$ is continuous.

Note that this interpretation of quantifiers is abandoned later by Turner (in [Turner' 1984]) and he decided to adopt the following clauses instead:

$[[\forall x \phi]]_{gut} = \begin{cases} 
1 & \text{if for each } d \in E_\infty \setminus \cup E_n, [[\phi]]_{g[d/x]} = 1 \\
0 & \text{if for some } d \in E_\infty \setminus \cup E_n, [[\phi]]_{g[d/x]} = 0 \\
\bot & \text{otherwise}
\end{cases}$
Of course working with Scott domains, you have always to check for continuity and this is the case with the new clauses. It can easily be proved that continuity does in fact hold and so we can still think of Scott domains as models.

We now describe the problem which made Turner move from the first definition of quantifiers to the second one. By adopting the first definition, we had: 

$$[[\exists x \phi]]_{\text{out}} = \begin{cases} 1 & \text{if for some } d \in E_\infty \setminus \cup E_n, [[\phi]]_{[d/x]_{\text{out}}} = 1 \\ 0 & \text{if for each } d \in E_\infty \setminus E_n, [[\phi]]_{[d/x]_{\text{out}}} = 0 \\ 1 & \text{otherwise} \end{cases}$$

As $$[[\phi]]$$ is continuous, therefore monotonic and as $$u \not\subseteq d$$ (where, as noted above, $$u$$ is the undefined) for each $$d \in D$$ then we get: 

$$(\forall d \in D)([[\phi]]_{[u/x]_{\text{out}}} = 1)$$ which implies: 

$$u = u \text{ iff } (\forall d \in D)(d = u).$$

That is absurd. We have to do something about this and the first solution that one thinks of is to exclude the undefined element from the quantifier clause. Therefore, instead of letting $$d$$ range over all of $$D$$, we let it range over $$D^*$$ (i.e. $$D \setminus \{u\}$$). But now Scott domains can no longer be models under this interpretation, for we no longer have $$[[\forall x \phi]]$$ is continuous. If we go back to the proof of continuity given above, we see that we had to use the undefined element in order to prove continuity. Turner, realising this, exploits an important aspect of the structure of Scott domains. We explained earlier the existence of finite and infinite elements in $$E_\infty$$ and said that for each element $$d$$ of $$E_\infty$$, $$d$$ is the limit of $$(e_n)$$ where $$e_n$$ belongs to $$E_n$$ and each $$E_n$$ is the domain of finite elements. The infinite (or ideal elements) are those which are in $$E_\infty \setminus \cup E_n$$. By restricting the quantification over these ideal elements only, we can prove again the closure of Scott models. However, by so restricting quantification, only infinite elements can be quantified over and finite elements are ignored.

3 Frege structures and nominalisation

Frege structures are not only a collection of collections of functions (as in the case of $$E_\infty$$), but they also have a certain logic which works on them, and whose availability solves also the problem of Section 1.1 of part I. Therefore, Frege structures solve both problems of section 1 of part I. In a Frege structure, quantifiers and other connectives are built inductively step by step so that at the fixed point one gets all these logical constants. This availability of logic, makes Frege structures attractive candidates for the semantics of nominalisation. Their other advantage is the type theory that can be built inside them which accommodates self application. In fact, we mentioned in 2.2.1 of part I that the theory of types was not adequate to the semantics of nominalisation. The typing constraints according to Church's type theory are too restrictive for nominalisation and we need to have functions which can apply to themselves or to items of the same type. Abandoning Church's type theory does not imply getting rid of all the typed theories. We can still keep to typed languages but make the typing adequate to deal with nominalisation. This section will develop a type theory based on Frege structures such that for any two types $$\sigma, \tau$$ the type $$\langle \sigma, \tau \rangle$$ is subsumed by the type $$\sigma$$. Some types will be circular or vacuous and they will be responsible for avoiding the paradoxes which
threaten theories that combine type freeness and logic. Basically, our method is to allow type freeness yet to restrict the abstraction of various formulae which belong to various types. Types can be basic or functional space types. Amongst the functional space types we have those types which are circular or vacuous. Abstraction is restricted to those formulae which when abstracted over will belong to a non circular, non vacuous type.

3.1 Polymorphic types

The set of types is the smallest set $\mathcal{T}$ such that

1. $p, t, e$ are in $\mathcal{T}$ are all distinct.
2. If $\sigma, \tau$ are in $\mathcal{T}$ then $<\sigma, \tau>$ is in $\mathcal{T}$.

The types defined in 1 are basic types, $p$ is the type of propositions, $t$ is the type of those true propositions (which are many according to the intensional framework) and $e$ is the type of objects. Of course not every object should be a proposition and not every proposition should be a truth. 2 gives the complex types. We impose a subsumption relation $\leq$ on the types as follows:

1. $\sigma \leq e$
2. $t \leq p$
3. $<\sigma, \tau> \leq \sigma$

We also require that $\leq$ be a partial ordering and therefore impose the following additional conditions:

4. $\sigma \leq \sigma$
5. if $\sigma \leq \tau$ and $\tau \leq \sigma$, then $\sigma = \tau$
6. if $\sigma \leq \tau$ and $\tau \leq \rho$ then $\sigma \leq \rho$
7. if $\tau \leq \rho$, then $<\sigma, \tau> \leq <\sigma, \rho>$
8. if $\tau \leq p$, then $<\sigma, \tau> \leq <\sigma, \tau>, \tau>$

1- 6 are obvious. As an example of 7, take the propositional functions which are of type $<e, p>$; these functions are also of type $<e, e>$. 8 is there to capture those circular types. In fact we have the following lemma:

**Lemma 3.1** If $\tau \leq p$, then $<\sigma, \tau> = <\sigma, \tau>, \tau> = <\sigma, \tau>, \tau> = \ldots$

$<\ldots<\sigma, \tau>, \tau>, \ldots, \tau>$

**Proof:** obvious from 3, 5 and 8. 

When $\sigma \leq \tau$, we say that $\tau$ subsumes, or is a more general type than, $\sigma$; intuitively, it means that any expression which is of type $\sigma$ is also of type $\tau$. Note that $e$ is the maximal element of the partial order, since it subsumes every type. We shall see that the subsumption relation plays a central role in polymorphism, and that there are models of such a typing system; that is, we will have functional domains $X \Rightarrow Y$ such that $(X \Rightarrow Y) \subseteq X$.

Our next task is to extend the definition of type so as to characterize the vacuous types, that is, the types which may be associated with empty domains. It is useful to first introduce the auxiliary notion of a p(propositional)-chain type. This is defined inductively as follows:
Definition 3.2 (P-Chain Type)

1. If $\rho \leq p$ and $\tau = e$ or $\tau = p$ or $\tau = t$ then $<\tau, \rho>$ is a p-chain type.
2. If $\tau$ is a p-chain type, and $\rho \leq p$ then $<\tau, \rho>$ is a p-chain type.

Example 3.3 $<e, p>, <p, p>, <t, p>, <<e, p>, p>$ (which is equal to $<e, p>$), $<<p, p>, p>$ (which is equal to $<p, p>$), $<<e, t>, <t, e>>$ ... are p-chain types. Moreover, whenever $\sigma$ is a p-chain type, then so are $<\sigma, t>, <\sigma, p>, <\sigma, t, \tau>>$ and $<\sigma, <p, \tau>>$ (for any type $\tau$).

Note however that the following are not p-chain types: $e, <e, e>, <e, <e, e>>, ...$

Vacuous types below will be associated with empty domains.

Definition 3.4 (Vacuous Types) $\sigma$ is a vacuous type iff:

1. $\sigma = <\tau, \rho>$ where $\tau$ and $\rho$ are p-chain types, and neither $\tau \leq p$ nor $\rho \leq p$ or
2. $\sigma = <\tau, \rho>$ where $\rho$ is a vacuous type, or
3. $\sigma =<\tau, \rho>$, where $\tau$ is vacuous.

From 2 and 3 we can conclude that a function space $<\sigma, \tau>$ is vacuous if its domain $\sigma$ is vacuous, using $<\sigma, \tau> \leq \sigma$.

Example 3.5 The following instances of $\sigma = <\tau, \rho>$ are vacuous:

- $\sigma = <<e, p>, <e, e>>$, by clause 1, since $\tau = p = <e, p>$ and not $<e, p> \leq p$.
- $\sigma = <<e, t>, <t, e>>, <<e, t>, <t, e>>$

There are p-chain types which are not vacuous; for example $<e, p>$. There are types that are vacuous but not p-chains. For example $<<e, p>, <e, p>>$. There are types which are neither vacuous nor p-chains. For example, $e, <e, e>, ...$

3.2 The Syntax of Tpol

The basic expressions of Tpol are as follows:

1. For each type $\sigma$, there exists an infinite number of constants. Constants of type $\sigma$ are referred to as $c_\sigma$
2. For each type $\sigma$, there exists an infinite number of variables. Variables of type $\sigma$ are referred to as $u_\sigma$.

Expressions of type $\sigma$, are defined recursively as follows:

1. $u_\sigma : \sigma$.
2. $c_\sigma : \sigma$.
3. If $\alpha : \tau, u : \sigma$ and $<\sigma, \tau>$ is a type which is not vacuous nor circular, then $\lambda u. \alpha : <\sigma, \tau>$.

12
4. If $\alpha : < \sigma, \tau >$ and $\beta : \sigma'$, where $\sigma' \leq \sigma$, then $app(\alpha, \beta) : \tau$.

5. If $\alpha : \sigma, \beta : \sigma'$ and $\sigma \leq \sigma'$, then $\alpha =_\sigma \beta : p$.

Suppose $\phi : p$ and $\psi : p$ then

6. $\neg \phi : p$ and $\neg \psi : t$ iff not ($\phi : t$).

7. $[\phi \lor \psi] : p$ and $[\phi \lor \psi] : t$ iff $\phi : t$ or $\psi : t$.

8. $[\phi \land \psi] : p$ and $[\phi \land \psi] : t$ iff $\phi : t$ and $\psi : t$.

9. $[\phi \supset \psi] : p$ and $[\phi \supset \psi] : t$ iff $\psi : t$ whenever $\phi : t$.

10. $[\phi \equiv \psi] : p$ and $[\phi \equiv \psi] : t$ iff $\phi : t$.

11. If $\phi : p$ and $u$ is a variable of any type $\sigma$ then $\forall u \phi : p$, and $\forall u \phi : t$ iff $\phi[u/u] : t$ for every constant $a : \sigma$.

12. If $\phi : p$ and $u$ is a variable of any type $\sigma$ then $\exists u \phi : p$, and $\exists u \phi : t$ iff $\phi[u/u] : t$ for some constant $a : \sigma$.

13. If $\sigma' \leq \sigma$, then $\alpha : \sigma'$ implies $\alpha : \sigma$.

Notice that we have placed a syntactic restriction of $\lambda$-abstraction to ensure that abstracts never have vacuous or circular types.

3.2.1 Axioms

In our system, self-application is only possible for those expressions which have a complex type; indeed, this is what is required by clause 4 of the syntax above.

- $(\alpha)$ $(\lambda x.\alpha) : < \sigma, \tau > = (\lambda y.\alpha[y/x]) : < \sigma, \tau >$, where $y$ is not free in $\alpha$.
- $(\beta)$ $app((\lambda x.\alpha) : < \sigma, \tau >, \beta : \sigma') = \alpha[\beta/x] : \tau$, if $\sigma' \leq \sigma$
- $(\gamma)$ If $\alpha_1 : < \sigma, \tau > = \alpha_2 : < \sigma, \tau >$ and $\beta_1 : \sigma = \beta_2 : \sigma$, then $app(\alpha_1, \beta_1) : \tau = app(\alpha_2, \beta_2) : \tau$
- $(\delta)$ If $\alpha_1 = \alpha_2 : \sigma$ and $\alpha_1 = \alpha_3 : \sigma$, then $(\alpha_2 = \alpha_3 : \sigma)$
- $(\epsilon)$ If $app(\alpha_1, x) : \tau = app(\alpha_2, x) : \tau$, then $\alpha_1 : < \sigma, \tau > = \alpha_2 : < \sigma, \tau >$ where $x : \sigma$ is not free in $\alpha_1, \alpha_2$ or any other assumption.
- $(\zeta)$ $app(\lambda x.\alpha_1, \beta_2) = app(\lambda x'.\alpha_1, \beta_2)$ where $x : \sigma, x' : \sigma', \sigma' \leq \sigma$, and $\beta_2$ is any term of type $\sigma'$.
- $(\theta)$ $(\alpha : \sigma =_\sigma \alpha : \sigma') \equiv (\alpha : \sigma =_\sigma a : \sigma')$ if $\sigma' \leq \sigma$.
- $(\rho)$ $(\alpha : \sigma = \alpha : \sigma) : t$
The following version of \( \eta \)-conversion is derivable:

If \( E : < \sigma, \sigma' > \) then \( \lambda x. Ex : < \sigma, \sigma' > = E : < \sigma, \sigma' > \) for \( x : \tau \) free in \( E \) and \( \tau \leq < \sigma, \sigma' > \)

**Proof**

\[
\begin{align*}
\lambda x. Ex &: < \tau, < \sigma, \sigma' > \leq \tau \leq < \sigma, \sigma' > \quad E &: < \sigma, \sigma' > \quad y &: \sigma' \text{ from } (\beta) \\
(\lambda x. Ex)y &: \sigma' = E[y/x] : \sigma' = E y : \sigma' \text{ from } (\varepsilon) \\
\lambda x. Ex &: < \sigma, \sigma' > = E &: < \sigma, \sigma' >
\end{align*}
\]

Axioms \((\alpha), (\beta), (\gamma)\) and \((\delta)\) are standard typed \( \lambda \)-calculus axioms. Axiom \((\varepsilon)\) is the extensionality axiom. It says that if \( \alpha_1 \) and \( \alpha_2 \) give the same results for the same arguments, then they are equal. Axiom \((\zeta)\) says that if \( f : A \rightarrow B \) and if \( f/A' \) is the restriction of \( f \) to \( A' \subseteq A \), then \( f \) and \( f/A' \) give the same results for all elements in \( A' \). Axiom \((\theta)\) says that if \( \alpha : \sigma' \) and if \( \sigma' \leq \sigma \) then saying that \( \alpha \) equals to itself in \( \sigma \) is the same as saying that \( \alpha \) is equal to itself in \( \sigma' \). Axiom \((\rho)\) is the reflexivity of \( = \).

### 3.2.2 Russell’s and Curry’s Paradoxes

Russell’s paradox does not occur here because paradoxical expressions of the form \( \lambda x. \neg \text{app}(x, x) \) are not well-formed. In fact, we have the following lemma:

**Lemma 3.6** If \( x \) is of type \( < \sigma, p > \), then \( \lambda x. \neg \text{app}(x, x) \) of type \( < \sigma, p >, p > \) is not well-formed.

**Proof** According to the definition of meaningful expressions, it is enough to show that \( < \sigma, p >, p > \) is a circular type. This is obvious from Lemma 3.1. \( \square \)

In fact, we have an even stronger lemma:

**Lemma 3.7** If \( x \) is of type \( < \sigma, \tau > \), where \( \tau \leq p \), then \( \lambda x. \neg \text{app}(x, x) \) of type \( < \sigma, \tau >, p > \) is not well-formed.

**Proof** Exactly as that of Lemma 3.6. \( \square \)

With these lemmas, if \( x : < \sigma, \tau > \), where \( \tau \leq p \), then \( \text{app}(x, x) \) is of type \( \tau \leq p \). Hence \( \neg \text{app}(x, x) \) is of type \( p \). But \( \lambda x. \neg \text{app}(x, x) \) is not well-formed in \( \text{Top} \), due to clause 3 in the definition of the expressions of a type, since its type, namely \( < < \varepsilon, p >, p > \), is circular.

Curry’s paradox comes from the presence of \((DT)\), \((MP)\) and \( \beta \) where \((DT)\) and \((MP)\) are as follows:

\[
\begin{align*}
(DT) & \quad \Gamma \cup \{\phi\} \vdash \psi \text{ implies } \Gamma \vdash \phi \rightarrow \psi, \\
(MP) & \quad \Gamma \vdash \phi \rightarrow \psi \text{ and } \Gamma \vdash \phi \text{ implies } \Gamma \vdash \psi,
\end{align*}
\]

If we take \( a \) to be the formula \( \lambda x. \text{app}(x, x) \rightarrow \bot \), then

1. \( \text{app}(a, a) = \text{app}(a, a) \rightarrow \bot \) by \( \beta \)-conversion
2. \( \text{app}(a, a) \vdash \text{app}(a, a) \), trivial
3. \( \text{app}(a, a) \vdash \text{app}(a, a) \rightarrow \bot \) by 1
4. \( \text{app}(a, a) \vdash \bot \) by \((MP)\) applied to 2 and 3
5. \( \text{app}(a, a) \vdash \bot \) by \((DT)\)
6. \( \vdash \text{app}(a, a) \) by 1
7. \( \vdash \bot \) by \((MP)\) applied to 5 and 6
However, our $(DT)$ and $(MP)$ have the following form:

$$(DT) \quad \Gamma \cup \{ \phi : t \} \vdash \psi : t \text{ implies } \Gamma \cup \{ \phi : p \} \vdash (\phi \to \psi) : t$$

$$(MP) \quad \Gamma \vdash (\phi \to \psi) : t \text{ and } \Gamma \vdash \phi : t \text{ implies } \Gamma \vdash \psi : t,$$

If we take $a$ to be the formula $\lambda x.(app(x,x) \to \bot)$, then

1. $app(a,a) = app(a,a) \to \bot$ by $\beta$-conversion
2. $app(a,a) : t \vdash app(a,a) : t$, trivial
3. $app(a,a) : t \vdash (app(a,a) \to \bot) : t$ by 1
4. $app(a,a) : t \vdash \bot : t$ by $(MP)$ applied to 2 and 3
5. $app(a,a) : p \vdash (app(a,a) \to \bot) : t$ by $(DT)$
6. $app(a,a) : p \vdash app(a,a) : t$ by 1
7. $app(a,a) : p \vdash \bot : t$ by $(MP)$ applied to 5 and 6

However, we cannot show that $app(a,a) : p$. In fact $\lambda x.(app(x,x) \to \bot)$ is not well formed due to Lemma 3.6 above as its type is $<\sigma', p, p>$. This is because if $x$ is of some type $\sigma$, since $app(x,x)$ has to be of type $p$, we can infer that $\sigma$ must be of the form $<\sigma', p>$. From this it follows that $a$ is of type $<\sigma', p, p>$, which is circular.

### 3.2.3 Models of Tpol

For the present paper we shall concentrate on $F_0$, $PROP$ and $SET$ (where $PROP \cap SET = \emptyset$) and then we shall construct domains inside $F_0$ which represent the types described in our theory Tpol.

Given domains $X, Y$ already in the Frege structure, we build new domains as follows:

$$(DOM) \quad X \Rightarrow Y = \{ x \in X : \forall x' \in X [app(x,x') \in Y] \}.$$

As a special case of $(DOM)$, the domain $(F_0 \Rightarrow PROP) = SET$ inside $F_0$ contains the nominals of propositional functions. Now let us see if the structure of types can be captured by the domains.

**Lemma 3.8** If $X, Y$ are domains, then $(X \Rightarrow Y) \subseteq X$.

**Proof** Obvious. □

**Lemma 3.9** If $X$ and $Y$ are domains built as above, then $Y \subseteq Y'$ implies $(X \Rightarrow Y) \subseteq (X \Rightarrow Y')$.

**Proof** If $x \in X \Rightarrow Y$, then $\forall x' \in X, app(x,x') \in Y$, by $(DOM)$. Since $Y \subseteq Y'$, it follows that $\forall x' \in X, app(x,x') \in Y'$ and so $x \in X \Rightarrow Y'$. □

**Lemma 3.10** If $X$ and $Y$ are domains built as above, then $X \subseteq X'$ implies $(X \cap (X' \Rightarrow Y)) \subseteq (X \Rightarrow Y)$.

**Proof** If $x \in X \cap (X' \Rightarrow Y)$ then $x \in X$, and $x \in (X' \Rightarrow Y)$; by $(DOM)$, $\forall x' \in X', app(x,x') \in Y$. Hence, we have both that $x \in X$ and, since $X \subseteq X'$, $\forall x' \in X, app(x,x') \in Y$. Therefore $x \in X \Rightarrow Y$. □
We now inductively define a relation $\sim$ between arbitrary domains $X$ and the domain $\text{SET}$. This relation is related to the notion of a p-chain type which we defined earlier. The relation $X \sim \text{SET}$ holds iff

1. $X = \text{SET}$, or
2. $X = (X' \Rightarrow Y')$ where $X' \leq \text{SET}$ and $Y' \leq \text{PROP}$.

We say that a domain $X$ is inductively predicable iff $X \sim \text{SET}$.

**Lemma 3.11** If $X \leq \text{SET}$ then $X \subseteq \text{SET}$.

Proof The proof is by an easy induction. If $X = \text{SET}$ then the property holds. Assume by induction that the property holds up to $X'$, and show that the property holds for $X = (X' \Rightarrow Y')$ where $X' \leq \text{SET}$. By Lemma 3.9, $(X' \Rightarrow Y) \subseteq X'$, and since $X' \subseteq \text{SET}$ by inductive hypothesis, we have by transitivity that $X \subseteq \text{SET}$. $\square$

The following lemma informs us that if $X, Y$ are inductively predicable then $X \Rightarrow Y$ is empty. When we give the denotation of our various types, we will find that the domains associated with vacuous types are always empty.

**Lemma 3.12** $\text{SET} \Rightarrow X$ is empty whenever $X \leq \text{SET}$.

Proof The proof is by induction on $X$:

1. If $X = \text{SET}$ then $\text{SET} \Rightarrow \text{SET}$ is empty, for the following reason. Suppose $x$ is in $\text{SET} \Rightarrow \text{SET}$. Then for every $x' \in \text{SET}$, $\text{app}(x, x') \in \text{SET}$. But $\text{app}(x, x')$ is also in $\text{PROP}$, by the definition of $x$ being a $\text{SET}$. Hence, $\text{PROP} \cap \text{SET}$ is not empty. Contradiction.

2. Assume $\text{SET} \Rightarrow X$ is empty for $X \leq \text{SET}$, and show that the domain $Y = \text{SET} \Rightarrow (X \Rightarrow Y)$ is empty. Suppose $Y$ is not empty, then if $x$ is in $\text{SET} \Rightarrow (X \Rightarrow Y)$, then for any $x'$ in $\text{SET}$, $\text{app}(x, x')$ is in $X \Rightarrow Y$. Hence $\text{app}(x, x') \in X$ for any $x' \in \text{SET}$. Hence $x$ is in $\text{SET} \Rightarrow X$ which is empty. Contradiction. $\square$

**Theorem 3.13** $X \Rightarrow Y$ is empty for $X, Y \leq \text{SET}$.

Proof The proof is by induction on $X \leq \text{SET}$. If $X = \text{SET}$ then the theorem holds according to Lemma 3.12. Assume the property holds for $X' \leq \text{SET}$, that is, the domain $X' \Rightarrow Y$ is empty for any $Y \leq \text{SET}$; we must show that $(X' \Rightarrow Y') \Rightarrow Y$ is empty for $Y' \subseteq \text{PROP}$. If $Z$ is not empty, i.e. there is some $a$ in $(X' \Rightarrow Y') \Rightarrow Y$, then $a$ is also in $X' \Rightarrow Y'$ and for all $x$ in $X' \Rightarrow Y'$, $\text{app}(a, x)$ is in $Y' \subseteq \text{PROP}$. But for all $x$ in $X' \Rightarrow Y'$, $\text{app}(a, x)$ is in $Y' \subseteq \text{SET}$. Hence $\text{app}(a, x)$ is in $\text{PROP} \cap \text{SET}$ which is empty, absurd. $\square$

**Example 3.14** The following domains are empty:

- $\text{SET} \Rightarrow \text{SET}$
- $\text{SET} \Rightarrow (\text{SET} \Rightarrow \text{PROP})$
- $(\text{SET} \Rightarrow \text{PROP}) \Rightarrow \text{SET}$ and
- every domain built recursively out of the above three using $\Rightarrow$.  

16
3.2.4 Semantics of Types

A model $M$ for Tpol is a quadruple $< F, \Rightarrow, C, D >$, where

1. $F$ is a Frege structure in which $PROP \cap SET = \emptyset$,
2. $\Rightarrow$ is as defined above by $(DOM)$,
3. The function $D$ which maps types into domains of $M$ is defined as follows:
   - $D_e = F_0$,
   - $D_p = PROP$,
   - $D_T = TRUTH$,
   - $D_{<\sigma,\tau>} = D_\sigma \Rightarrow D_\tau$, where $< \sigma, \tau >$ is non-vacuous.
4. $C$ is an interpretation function which takes any constant of type $\sigma$ to an object in $D_\sigma$.

We also assume the existence of an assignment function $g$ which takes any variable of a non-vacuous type $\sigma$ to an object in $D_\sigma$.

**Lemma 3.15** $D_{<\sigma,\tau>} = (D_\sigma \Rightarrow D_\tau) \subseteq D_\sigma$ where $< \sigma, \tau >$ is non-vacuous.

**Proof** Obvious by Lemma 3.8. □

**Lemma 3.16** If $D_\tau \subseteq D_\rho$ then $(D_\sigma \Rightarrow D_\tau) \subseteq (D_\sigma \Rightarrow D_\rho)$.

**Proof** If $a$ is in $(D_\sigma \Rightarrow D_\tau)$ then $(a \in D_\sigma)$ and $(\forall x \in D_\sigma)(app(a, x) \in D_\tau)$.

**Lemma 3.17** If $\sigma \leq \tau$ then $D_\sigma \subseteq D_\tau$.

**Proof** by induction on $\sigma \leq \tau$.
1. If $\sigma = e$ then $\tau = e$ and $D_\sigma = D_\tau$.
2. If $\sigma = t$ and $\tau = p$ then $D_\sigma = TRUTH$ and $D_\tau = PROP$.
3. If $\sigma = < \tau, \rho >$ then $D_\sigma = D_{<\tau,\rho>} \subseteq D_\tau$ by Lemma 3.15.
4. If $\tau \leq p$ then $D_{<\sigma,\tau>} \subseteq D_{<\sigma,\tau,\tau>}$
   Proof $(D_\sigma \Rightarrow D_\tau) \subseteq D_\sigma$. Hence by Lemma 3.10,
   $(D_\sigma \Rightarrow D_\tau) \cap (D_\sigma \Rightarrow D_\tau) \subseteq (D_\sigma \Rightarrow D_\tau) \Rightarrow D_\tau$.
   Hence $(D_\sigma \Rightarrow D_\tau) \subseteq (D_\sigma \Rightarrow D_\tau) \Rightarrow D_\tau$.
   Assume that $\tau \leq p$ implies $D_\tau \subseteq D_\rho$. Then $D_{<\sigma,\tau>} \subseteq D_{<\sigma,\rho>}$, by Lemma 3.16.
   Note that due to Lemma 3.16, if $< \sigma, \tau >$ is circular, then $D_{\sigma, \tau} = D_{<\sigma,\tau,\tau>}$. □

**Lemma 3.18** If $\sigma$ is a p-chain type and not $\sigma \leq p$ then $D_\sigma \leq SET$.

**Proof** The proof is by induction on $\sigma$.

If $\sigma = < e, \tau >$ then $D_\sigma \subseteq F_0 \Rightarrow PROP = SET \leq SET$.

Take $\sigma = < \tau, \tau' >$, where $\sigma$ is not $\leq p$ and $\tau$ is a p-chain type and property holds for $\tau$.

- case 1 not $\tau \leq p$, then $D_{<\tau,\tau'>} = D_\tau \Rightarrow D_\tau$, where $D_\tau \subseteq PROP$ and $D_\tau \leq SET$ by inductive hypothesis. Hence $D_{<\tau,\tau'>} \leq SET$. 17
• case 2 \( r \leq p \) then \( < r, r' > \leq r \leq p \). But it is not the case that \( < r, r' > \leq p \) absurd. Hence \( r \) is not \( \leq p \). □

Lemma 3.19 If \( \sigma \) is vacuous then \( D_\sigma \) is empty.

Proof If \( \sigma \) is vacuous, then \( \sigma = < r, \rho > \) where \( r \) and \( \rho \) are p-chain types not \( \leq p \) or either \( r \) or \( \rho \) is vacuous. If either is vacuous then nothing to prove. Else, \( D_\sigma = D_r \Rightarrow D_\rho \) where \( D_r, D_\rho \leq \text{SET} \) according to Lemma 3.18. Hence by Theorem 3.15, \( D_\sigma \) is empty. □

4 COMPARISON AND CONCLUSION

In this part, we showed that Frege structures provide a solution to both problems; we provided a type theory where any function belongs to its domain and hence the theory is a suitable framework for nominalisation. Now we assess further the advantages one obtains with Frege structures. We start with type freeness and the fact that \( \text{SET} \) is isomorphic to Propositional functions \( F_0 \rightarrow \text{PROP} \) and that \( \text{SET} \subset F_0 \). Also, we have the two following functionals:

\[
\parallel \parallel : \text{SET} \rightarrow PF_1 \\
\lambda : PF_1 \rightarrow \text{SET}.
\]

If we assume that the interpretation of verbs takes place in \( F_i \) for \( i \geq 1 \) and thus that \( [[\text{walk}]] \) is in \( F_1 \), then we get: \( [[\text{to walk}]]g = \lambda ([[\text{walk}]]g) \).

Now it is straightforward to interpret things like \( \text{to walk hurts} \), for: \( [[\text{to walk hurts}]]g = [[\text{hurt}]]g([[\text{to walk}]]g) = [[\text{hurt}]]g(\lambda ([[\text{walk}]]g)) \).

The advantage of what we just offered lies in the elegance of classifying the denotation of our items. With Montague's and Turner's approaches, one has always to check whether the denotation of an item is in the right domain. With our approach, we do not need to check whether \( [[\text{to walk}]]g \) is in \( F_0 \) or not using some confusing domain equations. All we had to say was that \( [[\text{walk}]]g \) is in \( F_1 \); therefore \( \lambda [[\text{walk}]]g \) is in \( F_0 \). This actually seems to be an encouraging advantage about Frege structures: nominalisation and self reference are a natural process inside the Frege structure. It also seems that we have real application, unlike in Scott domains where application is only through the isomorphic embedding. This is because instead of interpreting things as above into \( F_i \), for \( i \geq 0 \), we can restrict everything to \( F_0 \) obtaining \( [[\text{fun is fun}]]g = \text{pred}([[\text{fun}]]g, [[\text{fun}]]g) \).

Therefore it seems that by using Frege structures we get the following advantages over Scott domains,

1. Real self application
2. Less cumbersome checking for the right typing than that involved with Scott domains. It is mainly checking the propositionhood of various items to obtain the type of the resulting item.
3. No redundant semantic types
4. Nominalisation seems to flow naturally
5. Quantification

For the sake of completeness, we mention a new approach to a theory of properties proposed by Turner (in [Turner 1987]) which abandons completely the use of Scott domains. Turner's new theory is one which starts from Frege's comprehension principle and restricts
it in such a way that the paradox is no longer derivable. 

Turner, like Frege, starts with a first order theory which has a pairing system and adds to this theory a new operator \( p \) (to serve as the predication operator) together with the lambda operator. Then in this case, if one assumes full classical logic and Frege’s comprehension principle, one will certainly derive the paradox; for, take \( a = \lambda x. \neg p(x, x) \), then \( p(a, a) \leftrightarrow \neg p(x, x)[a/x] \leftrightarrow \neg p(a, a) \). Contradiction.

Of course, the problem does not come from contraction, i.e. \( p(\lambda x. A, t) \to A(t, x) \) is always true. But the converse implication (i.e. expansion) is problematic. This is due to negation, i.e. if \( A \) is atomic then we can accept \( A(t, x) \to p(\lambda x. A, t) \). But we cannot accept it when \( A \) is like Russell’s property, an atomic term proceeded by a negation sign. This is exactly what guides Turner in setting his theory. For the theory now will have the following axioms replacing Frege’s comprehension principle:

- \( (E1) \quad A(t, x) \to p(\lambda x. A, t) \) when \( A \) is atomic.
- \( (R) \quad p(\lambda x. A, t) \to A(t, x) \).
- \( (I) \quad p(\lambda x. p(\lambda y. A, x), u) \to p(\lambda y. p(\lambda x. A, u), t) \)

Now the abandonment of Frege’s full comprehension axiom will impose the use of two logics, one inside the predication operator in addition to the usual one for wffs. This is due to the fact that breaking the equivalence between \( p(\lambda x. A, t) \) and \( A(t, x) \) will disconnect the reasoning about wffs and properties. To build models for \( T \) above, one uses the fixed point operator to turn an orclinary model of the first order theory into a model which will validate in it as many instances of the comprehension axiom as possible. It will of course validate only the safe instances whereas the paradoxical ones will oscillate in truth-values. The inductive step to build the model should be obvious. As an example, one can start with the first order model, and an operator \( PI \) which is empty at the beginning. Then at the next step, extend \( PI \) to also contain the pairs \( < [\lambda x. A], [t]_{\text{p}} > \) such that \( [[A]]_0[[[t]]_{\text{p}}/x] = 1 \) and so on until one gets a limit ordinal \( \chi \) where \( PI \) then is to have in it all the pairs \( < e, d > \) such that for some ordinal smaller than this \( \chi \), \( < e, d > \) belongs to all the intermediate \( PI \)'s. Now we no longer have a full comprehension principle and we cannot do with properties what we can do with formulae. But there are still a great deal of things that one can identify between properties and wffs; for example, from \( P(\lambda x. A, t) \) and \( P(\lambda x. B, t) \) one can derive \( p(\lambda x. A \land B, t) \). Turner showed however that theories of Frege structures are weaker than his theory of properties which is a fact that may stand to our advantage for the following reasons. Firstly, Turner can prove at least as much in his theory as one can in a theory based on Frege structures. Secondly, Turner is paying a price for the strength of his theory — mainly his use of two logics (internal and external) rather than one only. On balance it seems better to use a theory based on Frege structures for properties. Doing so gains the advantages of Turner without the complications.

From the point of view of typing, whereas I use a type free theory, Cocchiarella uses a second order one. There are however some similarities and differences in these two ways of typing that I would like to illustrate. According to axiom (9) under 1.1.2 of Part I, we have \( ME_n \subseteq ME_0 \) for all \( n > 1 \), where \( ME_n \) are the meaningful expressions of any type \( n \). For us, we have that \( ME_n \subseteq ME_0 \) for any \( 1 \leq n \) but the pictures of both approaches are quite different. According to our approach these types are related to each other in a chain like way. That is \( ME_n \subseteq ME_{n-1} \ldots \subseteq ME_0 \). For Cocchiarella we have that each \( ME_n \subseteq ME_0 \) for \( n > 1 \), yet no relation exists between \( ME_n \) and \( ME_m \) for \( n \neq m \). Also for Cocchiarella, propositions are not included in objects, even though they can be embedded in \( ME_0 \) by axiom (8) under the same paragraph. Hence Cocchiarella’s whole structure can be understood as a collection of objects, which has a denumerably infinite number of subcollections called
functions but where propositions are outside the domain of objects and can be mapped into it. This structure for Cocchiarella is not a structure of types in the sense that we have in the typing structure in [Kamareddine 1988]. In fact everything that Cocchiarella has so far we have; as can be seen in [Kamareddine 1988], a Frege structure is $F_0, \ldots, F_n$, where $F_0$, is the collection of objects, $F_k$ is the collection of $k$-ary functions and each of these $F_k$, can be embedded in $F_0$, by $\lambda x$. What we have in addition is a typing system constructed inside $F_0$, which cannot be found in Cocchiarella's theory. Also, our system is first order in that the quantification over objects and functions is the same, whereas Cocchiarella’s system is second order.
