Abstract

This paper confirms a conjecture of Bergstra and Klop’s from 1984 by establishing that the process algebra obtained by adding an auxiliary operator proposed by Hennessy in 1981 to the recursion free fragment of Milner’s Calculus of Communicating Systems is not finitely based modulo bisimulation equivalence. Thus Hennessy’s merge cannot replace the left merge and communication merge operators proposed by Bergstra and Klop, at least if a finite axiomatization of parallel composition is desired.

2000 Mathematics Subject Classification: 08A70, 03B45, 03C05, 68Q10, 68Q45, 68Q55, 68Q70.
Keywords and Phrases: Concurrency, process algebra, CCS, bisimulation, Hennessy’s merge, left merge, communication merge, parallel composition, equational logic, complete axiomatizations, non-finitely based algebras.
1 Introduction

Process algebras are prototype description languages for reactive systems that arose from the pioneering work of figures like Bergstra, Hoare, Klop and Milner. Well known examples of such languages are ACP [7], CCS [26], CSP [23] and Meije [5]. These algebraic description languages for processes differ in the basic collection of operators that they offer for building new process descriptions from existing ones. However, since they are designed to allow for the description and analysis of systems of interacting processes, they all contain some form of parallel composition (also known as merge) operator allowing one to put two process terms in parallel with one another. These operators usually interleave the behaviours of their arguments, and allow for some form of synchronization between them. For example, Milner’s CCS offers the binary operator \(|\)

\[
(\begin{array}{ll}
    x \xrightarrow{\mu} x' \\
    y \xrightarrow{\mu} y'
\end{array}
\)

\[
\frac{x | y \xrightarrow{\tau} x' | y'}{x \xrightarrow{\alpha} x', y \xrightarrow{\bar{\alpha}} y'}
\]

(In the above rules, the symbol \(\mu\) stands for an action that a process may perform, \(\alpha\) and \(\bar{\alpha}\) are two observable actions that may synchronize, and \(\tau\) is a symbol denoting the result of their synchronization.)

Although the above rules describe the behaviour of the parallel composition operator in very intuitive fashion, the equational characterization of this operator is not straightforward. In their seminal paper [22], Hennessy and Milner offered, amongst a wealth of other classic results, a complete equational axiomatization of bisimulation equivalence [31] over the recursion free fragment of CCS. The axiomatization proposed by Hennessy and Milner \textit{ibidem} dealt with parallel composition using the so-called \textit{expansion law}—a law that, intuitively, allows one to obtain a term describing the initial transitions of the parallel composition of two terms whose initial transitions are known. This law can be expressed as a conditional equation thus

\[
x = \sum_{i \in I} \mu_i x_i, \quad y = \sum_{j \in J} \gamma_j y_j
\]

\[
x | y = \sum_{i \in I} \mu_i (x_i | y) + \sum_{j \in J} \gamma_j (x | y_j) + \sum_{i \in I, j \in J, \mu_i = \gamma_j} \tau (x_i | y_j)
\]

(where \(I\) and \(J\) are two finite index sets, and the \(\mu_i\) and \(\gamma_j\) are actions), and is nothing but an equational formulation of the aforementioned rules describing the operational semantics of parallel composition.

As already remarked, the expansion law, however, is a conditional equation, which may alternatively be viewed as an equation schema with a countably infinite number of instances. This raised the question of whether the parallel composition operator could be axiomatized in bisimulation semantics by means of a finite collection of equations. This question was answered positively by Bergstra and Klop, who gave in [8] a finite equational axiomatization of the merge operator in terms of the auxiliary left merge and communication merge operators. Moller showed
in [29, 30] that strong bisimulation equivalence is not finitely based over CCS and PA without the left merge operator. (The process algebra PA [8] contains a parallel composition operator based on pure interleaving without communication—viz. an operator described by the first two rules in (1)—and the left merge operator.) Thus auxiliary operators are necessary to obtain a finite axiomatization of parallel composition.

In the arguably less well known paper [21], Hennessy proposed an axiomatization of observation congruence [22] (also known as rooted weak bisimulation) and timed congruence (also known as split-2 congruence) over a CCS-like recursion free process language. (It is worth noting that, although this paper was published in 1988 by the SIAM Journal on Computing as [21], the results reported ibidem were actually obtained in 1981–1982.) Those axiomatizations used an auxiliary operator, denoted \( \gamma \) by Hennessy, that is essentially a combination of the left and communication merge operators as its behaviour is described by the first and the last rule in (1). Apart from having soundness problems (see the reference [1] for a general discussion of this problem, and corrected proofs of Hennessy’s results), the proposed axiomatization of observation congruence offered in op. cit. is infinite, as it used a variant of the expansion theorem from [22]. This led Bergstra and Klop to write in [8, page 118] that:

“It seems that \( \gamma \) does not have a finite equational axiomatization.”

(In op. cit. Bergstra and Klop used \( \gamma \) to denote Hennessy’s merge.) To the best of our knowledge, the non-finite axiomatizability of Hennessy’s merge has, however, never been proven. The main result in this paper confirms this conjecture of Bergstra and Klop’s by showing that, in the presence of two distinct complementary actions, it is impossible to provide a finite axiomatization of the recursion free fragment of CCS modulo bisimulation using Hennessy’s merge operator \( \gamma \). We believe that this result further reinforces the status of the left merge and the communication merge operators as auxiliary operators in the finite equational characterization of parallel composition in bisimulation semantics.

The aforementioned negative result holds in a very strong form. Indeed, we prove that no finite collection of equations over the language we study that are sound with respect to bisimulation equivalence can prove all of the sound closed equalities of the form

\[
e_n : \quad a0 \not\approx p_n \approx ap_n + \sum_{i=0}^{n} \tau a^i \quad (n \geq 0),
\]

where the terms \( p_n \) are defined thus:

\[
p_n = \sum_{i=0}^{n} \bar{a}a^i \quad (n \geq 0).
\]

The proof of our main result is given along proof theoretic lines that have their roots in those for the aforementioned results of Moller’s to the effect that bisimulation equivalence is not finitely based over the recursion free fragment of CCS.
However, the presence of possible synchronizations in the terms used in the family of equations $e_n$ is necessary for our result, and requires careful attention in the proofs. (Indeed, in the absence of synchronization, Hennessy’s merge reduces to Bergstra and Klop’s left merge operator, and thus affords a finite equational axiomatization.) In particular, the infinite family of equations $e_n$ and our arguments based upon it exploit the inability of any finite axiom system $E$ that is sound with respect to bisimulation equivalence to “expand” the synchronization behaviour of terms of the form $p \parallel q$, for terms $q$ that, like the terms $p_n$ above eventually do, have a number of inequivalent “summands” that is larger than the maximum size of the terms mentioned in equations in $E$. As in the original arguments of Moller’s, the root of this problem can be traced back to the fact that the choice operator $+$ distributes with respect to $\parallel$ in the first argument, but not in the second.

**Related Work** The equational characterization of different versions of the parallel composition operator is a classic topic in the theory of computation, and this paper joins the aforementioned seminal references in contributing to this line of research. In particular, the process algebraic literature abounds with results on equational axiomatizations of various notions of behavioural equivalences or preorders over languages incorporating some notion of parallel composition—see, e.g., the textbooks [7, 20, 26] and the classic papers [8, 22, 25] for general references. Early $\omega$-complete axiomatizations are offered in [19, 28]. More recently, Fokkink and Luttik have shown in [17] that the process algebra PA [8] affords an $\omega$-complete axiomatization that is finite if so is the underlying set of actions.

An analysis of the reasons why operators like the left merge and the communication merge are equationally well behaved in bisimulation semantics has led to general algorithms for the generation of (finite) equational axiomatizations for behavioural equivalences from their operational semantics—see, e.g., [3, 6] and the references in [4] for further details.

Parallel composition appears as the shuffle operator in the time-honoured theory of formal languages. Not surprisingly, the equational theory of shuffle has received considerable attention in the literature. Here we limit ourselves to mentioning some results that have a special relationship with process theory.

In [35], Tschantz offered a finite equational axiomatization of the theory of languages over concatenation and shuffle, solving an open problem raised by Pratt. In proving this result he essentially rediscovered the concept of pomset [33]—a model of concurrency based on partial orders whose algebraic aspects have been investigated by Gischer in [18]—, and proved that the equational theory of series-parallel pomsets coincides with that of languages over concatenation and shuffle. The argument adopted by Tschantz was based on the observation that series-parallel pomsets may be coded by a suitable homomorphism into languages, where the series and parallel composition operators on pomsets are modelled by the concatenation and shuffle operators on languages. Tschantz’s technique of coding pomsets with languages homomorphically was further extended in the papers [10, 12, 13] to deal
with several other operators, infinite pomsets and infinitary languages, and sets of
pomsets. The axiomatizations by Gischer and Tschantz have later been extended
in [13, 16] to a two-sorted language with \( \omega \) powers of the concatenation and parallel
composition operators. The axiomatization of the algebra of pomsets resulting
from the addition of these iteration operators is, however, necessarily infinite be-
cause, as shown in op. cit. no finite collection of equations can capture all the sound
equalities involving them. (See [14] for closely related developments.)

The results of Moller’s on the non-finite axiomatizability of bisimulation equiv-
alanlity over the recursion free fragment of CCS and PA without the left merge
operator given in [29, 30] are paralleled in the world of formal language theory
by those offered in [9, 11, 15]. In the first of those references, Bloom and ´Esik
proved that the valid inequations in the algebra of languages equipped with con-
catenation and shuffle have no finite basis. ´Esik and Bertol showed in [15] that
the equational theory of union, concatenation and shuffle over languages has no fi-
nite first-order axiomatization relative to the collection of all valid inequations that
hold for concatenation and shuffle. Hence the combination of some form of parallel
composition, sequencing and choice is hard to characterize equationally both in
the theory of languages and in that of processes. Moreover, Bloom and ´Esik have
shown in [11] that the variety of all languages over a finite alphabet ordered by in-
clusion with the operators of concatenation and shuffle, and a constant denoting the
singleton language containing only the empty word is not finitely axiomatizable by
first-order sentences that are valid in the the equational theory of languages over
concatenation, union and shuffle.

Roadmap of the Paper  We begin by presenting preliminaries on the language
CCS\(_H\)—the extension of CCS with Hennessy’s merge operator—and equational
logic (Sect. 2). In particular, Sect. 2.2 offers a detailed discussion of the simplifying
assumptions we shall make, without loss of generality, on the equational axiom
systems that we shall consider in the rest of the paper. Our main result on the non-
existence of a finite equational axiomatization for bisimulation equivalence over
the language CCS\(_H\) (Theorem 3.1) is stated in Sect. 3. There we show how to
reduce the proof of Theorem 3.1 to that of a proposition (Proposition 3.2) to the
effect that no finite axiom system over the fragment of the language CCS\(_H\) that
does not use the parallel composition operator can prove all of the aforementioned
equations \( e_n \). The following two technical sections of the paper, viz. Sects. 4 and 5,
are entirely devoted to a detailed proof of Proposition 3.2. The paper ends with
some concluding remarks (Sect. 6).

2 Preliminaries

We begin by introducing the basic definitions and results on which the technical
developments to follow are based.

2.1 The language CCS$_H$

The language for processes we shall consider in this paper, henceforth referred to as CCS$_H$, is obtained by adding Hennessy’s merge operator from [21] to the recursion, restriction and relabelling free subset of Milner’s CCS [26]. This language is given by the following grammar:

$$t ::= x \mid 0 \mid at \mid \bar{a}t \mid \tau t \mid t + t \mid t \mid t \mid t,$$

where $x$ is a variable drawn from a countably infinite set $V$, $a$ is an action, and $\bar{a}$ is its complement. We assume that the actions $a$ and $\bar{a}$ are distinct. Following Milner [26], the action symbol $\tau$ will result from the synchronized occurrence of the complementary actions $a$ and $\bar{a}$. We let $\mu \in \{a, \bar{a}, \tau\}$ and $\alpha \in \{a, \bar{a}\}$. As usual, $\bar{\bar{a}} = a$. We shall use the meta-variables $t, u, v, w$ to range over process terms, and write $\text{var}(t)$ for the collection of variables occurring in the term $t$. The size of a term is the number of operator symbols in it. A process term is closed if it does not contain any variables. Closed terms will be typically denoted by $p, q, r$.

In order to obtain the negative results offered in this paper, it will be sufficient to consider the above language. The results we shall present in what follows carry over unchanged to a setting with an arbitrary number of actions, and corresponding unary prefixing operators.

A (closed) substitution is a mapping from process variables to (closed) CCS$_H$ terms. For every term $t$ and (closed) substitution $\sigma$, the (closed) term obtained by replacing every occurrence of a variable $x$ in $t$ with the (closed) term $\sigma(x)$ will be written $\sigma(t)$.

In the remainder of this paper, we let $a^0$ denote 0, and $a^{m+1}$ denote $a(a^m)$.

The SOS rules for all of the classic CCS operators are standard, and may be found in Table 1. Those for Hennessy’s $\mid$ formalize the intuition that this operator is indeed a combination of the left and communication merge operators, and are:

$\hline$
<table>
<thead>
<tr>
<th>Rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$x \xrightarrow{\mu} x'$</td>
<td>$x \xrightarrow{\mu} x'$</td>
</tr>
<tr>
<td>$y \xrightarrow{\alpha} y'$</td>
<td>$y \xrightarrow{\alpha} y'$</td>
</tr>
<tr>
<td>$x \mid y \xrightarrow{\mu} x' \mid y$</td>
<td>$x \mid y \xrightarrow{\mu} x' \mid y'$</td>
</tr>
</tbody>
</table>

These transition rules give rise to transitions between CCS$_H$ terms. The operational semantics for CCS$_H$ is thus given by the labelled transition system [24] whose
states are $CCS_H$ terms, and whose labelled transitions are those that are provable using the rules. As usual, for each term $t$ and action $\mu$, we write $t \xrightarrow{\mu} t'$ if $t \xrightarrow{\mu} t'$ holds for some term $t'$.

The transition relations $\xrightarrow{\mu}$ naturally compose to determine the possible effects that performing a sequence of actions may have on a $CCS_H$ term.

**Definition 2.1** For a sequence of actions $s = \mu_1 \cdots \mu_k$ ($k \geq 0$), and $CCS_H$ terms $t, t'$, we write $t \xrightarrow{s} t'$ iff there exists a sequence of transitions

$$t = t_0 \xrightarrow{\mu_1} t_1 \xrightarrow{\mu_2} \cdots \xrightarrow{\mu_k} t_k = t'.$$

If $t \xrightarrow{s} t'$ holds for some $CCS_H$ term $t'$, then $s$ is a trace of $t$.

The depth of a term $t$, written $\text{depth}(t)$, is the length of the longest trace it affords.

The depth of closed terms can also be characterized inductively thus:

- $\text{depth}(0) = 0$
- $\text{depth}(\mu p) = 1 + \text{depth}(p)$
- $\text{depth}(p + q) = \max\{\text{depth}(p), \text{depth}(q)\}$
- $\text{depth}(p \mid q) = \text{depth}(p) + \text{depth}(q)$
- $\text{depth}(p \not\mid q) = \begin{cases} 0 & \text{if } \text{depth}(p) = 0, \\ \text{depth}(p) + \text{depth}(q) & \text{otherwise}. \end{cases}$

In what follows, we shall sometimes need to consider the possible origins of a transition of the form $\sigma(t) \xrightarrow{\alpha} p$, for some action $\alpha \in \{a, \bar{a}\}$, closed substitution $\sigma$, $CCS_H$ term $t$ and closed term $p$. Naturally enough, we expect that $\sigma(t)$ affords that transition if $t \xrightarrow{\alpha} t'$, for some $t'$ such that $p = \sigma(t')$. However, the above transition may also derive from the initial behaviour of some closed term $\sigma(x)$, provided that the collection of initial moves of $\sigma(t)$ depends, in some formal sense, on that of the closed term substituted for the variable $x$. To fully describe this situation, we introduce the auxiliary notion of configuration of a $CCS_H$ term. To this end, we assume a set of symbols

$$V_d = \{x_d \mid x \in V\}$$

disjoint from $V$. Intuitively, the symbol $x_d$ (read “during $x$”) will be used to denote that the closed term substituted for variable $x$ has begun executing.

**Definition 2.2** The collection of $CCS_H$ configurations is given by the following grammar:

$$c ::= t \mid x_d \mid c \mid t \mid t \mid c,$$

where $t$ is a $CCS_H$ term, and $x_d \in V_d$.

For example, the configuration $x_d \mid (a0 \not\mid x)$ is meant to describe a state of the computation of some term in which the (closed term substituted for the) occurrence of variable $x$ on the left-hand side of the $\mid$ operator has begun its execution, but the
Table 2: SOS Rules for the Auxiliary Transitions \( \frac{x}{x} \to (x \in V) \)

\[
\begin{array}{ccc}
\frac{x}{x} \to x_d & \frac{t}{t} \to c & \frac{u}{u} \to c \\
\frac{t}{t + u} \to c & \frac{u}{t + u} \to c & \frac{t}{u} \to c \\
\frac{u}{t} \to c &!\frac{t}{u} \to c &!\frac{t}{u} \to c \\
\frac{t}{u} \to c & \frac{t}{u} \to c & \frac{t}{u} \to c \\
\end{array}
\]

one on the right-hand side has not. We shall consider the symbols \( x_d \) as variables, and use the notation \( \sigma⎡x_d \mapsto p⎤\), where \( \sigma \) is a closed substitution and \( p \) is a closed CCS_H term, to stand for the substitution mapping \( x_d \) to \( p \), and acting like \( \sigma \) on all of the variables in \( V \).

The way in which the initial behaviour of a term may depend on that of the variables that occur in it is formally described by an auxiliary transition relation whose elements have the form \( t \xrightarrow{x} c \), where \( t \) is a term, \( x \) is a variable, and \( c \) is a configuration. The SOS rules defining these transitions are given in Table 2.

**Lemma 2.1** Assume that \( t \) is a CCS_H term, \( \sigma \) is a closed substitution and \( \alpha \in \{a, \bar{a}\} \). Then the following statements hold:

1. If \( t \xrightarrow{\alpha} t' \), then \( \sigma(t) \xrightarrow{\alpha} \sigma(t') \).
2. Assume that \( t \xrightarrow{x} c \) and \( \sigma(x) \xrightarrow{\alpha} p \), for some closed term \( p \). Then \( \sigma(t) \xrightarrow{\alpha} \sigma[x_d \mapsto p](c) \).
3. Assume that \( \sigma(t) \xrightarrow{\alpha} p \), for some closed term \( p \). Then
   - either \( t \xrightarrow{\alpha} t' \) for some \( t' \) such that \( p = \sigma(t') \)
   - or \( t \xrightarrow{x} c \) and \( \sigma(x) \xrightarrow{\alpha} q \), for some variable \( x \), configuration \( c \) and closed term \( q \) such that \( \sigma[x_d \mapsto q](c) = p \).

In this paper, we shall consider the language CCS_H modulo bisimulation equivalence \([26, 31]\).

**Definition 2.3** Bisimulation equivalence (also sometimes referred to as bisimilarity), denoted by \( \equiv \), is the largest symmetric relation over closed CCS_H terms such that whenever \( p \equiv q \) and \( p \xrightarrow{\mu} p' \), then there is a transition \( q \xrightarrow{\mu} q' \) with \( p' \equiv q' \).

If \( p \equiv q \), then we say that \( p \) and \( q \) are bisimilar.

It is well-known that, as the name suggests, bisimulation equivalence is indeed an equivalence relation (see, e.g., the references \([26, 31]\)). Moreover, two bisimulation equivalent terms over the language CCS_H afford the same finite non-empty set of traces, and have therefore the same depth. Since the SOS rules defining the operational semantics of the language CCS_H are in de Simone’s format \([34]\), we have that:
Fact 2.1 Bisimulation equivalence is a congruence over the language CCS_H.

Bisimulation equivalence is extended to arbitrary CCS_H terms thus:

Definition 2.4 Let t, u be CCS_H terms. Then t \equiv u iff \sigma(t) \equiv \sigma(u) for every closed substitution \sigma.

For instance, we have that 0 \nmid x \equiv 0 because 0 \nmid p affords no transition, for each closed term p.

Definition 2.5 We say that a term t has a 0 factor if it contains a subterm of the form t' \nmid t'' or t' \nmid t'', where either t' or t'' is bisimilar to 0.

For example, the terms a(0 \mid x) and (0 \nmid x) \mid y have a 0 factor.

2.2 Equational Logic

An axiom system is a collection of equations t \equiv u over the language CCS_H. An equation p \equiv q is derivable from an axiom system E, notation E \vdash p \equiv q, if it can be proven from the axioms in E using the rules of equational logic (viz. reflexivity, symmetry, transitivity, substitution and closure under CCS_H contexts):

\[
\begin{align*}
  t \equiv t & \quad t \equiv u \quad u \equiv t \quad t \equiv v \\
  t \equiv u & \quad u \equiv v \quad t \equiv u \\
  \sigma(t) \equiv \sigma(u) & \quad \mu t \equiv \mu u \\
  t \equiv u & \quad t' \equiv u' \\
  t + t' \equiv u + u' & \quad \mu t \equiv \mu u \\
  t \nmid t' \equiv u \nmid u' & \quad \mu t \equiv \mu u \\
  t \nmid t' \equiv u \nmid t' \equiv u' & \quad \mu t \equiv \mu u \\
\end{align*}
\]

Without loss of generality one may assume that substitutions happen first in equational proofs, i.e., that the rule

\[
\frac{t \equiv u}{\sigma(t) \equiv \sigma(u)}
\]

may only be used when (t \equiv u) \in E. In this case \sigma(t) \equiv \sigma(u) is called a substitution instance of an axiom in E.

Definition 2.6 We call a closed substitution \sigma substantial if depth(\sigma(x)) > 0 for each variable x.

For reasons of technical convenience, in the proofs of our non-finite axiomatizability results presented in this paper we shall only allow for the use of closed substantial substitutions in the rule of substitution. This does not limit the generality of those results because every finite equational axiomatization E can be converted into a finite equational axiomatization E' such that the closed substitution instances of the axioms of E are the same as the closed substantial substitution instances of the axioms of E' (when equating any closed subterm of depth 0 with 0). This is
Table 3: Some Axioms for $\text{CCS}_H$

| A1   | $x + y \approx y + x$ |
| A2   | $(x + y) + z \approx x + (y + z)$ |
| A3   | $0 + x \approx x$ |
| A4   | $x + 0 \approx x$ |
| HM1  | $0 \mid x \approx 0$ |
| HM2  | $x \mid 0 \approx x$ |
| M1   | $x \mid 0 \approx x$ |
| M2   | $0 \mid x \approx x$ |

done by including in $E'$ any equation that can be obtained from an equation in $E$ by replacing all occurrences of any number of variables by 0. (The identification of each $\text{CCS}_H$ term that is bisimilar to 0 with 0 can be done equationally using three equations. See Fact 2.2 to follow.)

**Definition 2.7** We say that a substitution $\sigma$ is a 0-substitution iff $\sigma(x) \neq x$ implies that $\sigma(x) = 0$, for each variable $x$.

An axiom system $E$ is closed with respect to 0-substitutions iff $\sigma(t) \approx \sigma(u)$ is contained in $E$, for each 0-substitution $\sigma$, if so is $t \approx u$.

**Simplifying Assumption 1** In the remainder of this paper, we shall always tacitly assume that equational axiom systems are closed with respect to 0-substitutions.

Note that if $E$ is a finite axiom system, then so is its closure with respect to 0-substitutions. In fact, for each term $t$, the collection of terms

$$\{\sigma(t) \mid \sigma \text{ a 0-substitution}\}$$

is finite.

Moreover, by postulating that for each axiom in $E$ also its symmetric counterpart is present in $E$, one may assume that applications of symmetry happen first in equational proofs.

**Simplifying Assumption 2** In the remainder of this paper, we shall also tacitly assume that our equational axiom systems are closed with respect to symmetry.

**Definition 2.8** An equation $t \approx u$ over the language $\text{CCS}_H$ is sound with respect to $\leftrightarrow$ iff $t \leftrightarrow u$. An axiom system is sound with respect to $\leftrightarrow$ iff so is each of its equations.

An example of a collection of equations over the language $\text{CCS}_H$ that are sound with respect to $\leftrightarrow$ is given in Table 3. In addition, the following law, which ex-
presses the parallel composition operator in terms of Hennessy’s merge, is easily seen to be sound with respect to \(\equiv\):

\[
x | y \equiv (x \parallel y) + (y \parallel x)
\]  \hspace{1cm} (2)

The axioms A4, HM1 and M1 in Table 3 (used from left to right) are enough to establish that each CCS\(_H\) term that is bisimilar to \(0\) is also provably equal to \(0\). Since we feel that the proof of this little result is instructive, we now proceed to present its sketch.

**Fact 2.2** Let \(t\) be a CCS\(_H\) term. Then \(t \equiv 0\) if, and only if, the equation \(t \approx 0\) is provable using axioms A4, HM1 and M1 in Table 3 from left to right.

**Proof:** The “if” implication is an immediate consequence of the soundness of the equations A4, HM1 and M1 with respect to \(\equiv\). To prove the “only if” implication, define, first of all, the collection NIL of CCS\(_H\) terms as the set of terms generated by the following grammar:

\[
t ::= 0 | t + t | t | t \parallel u,
\]

where \(u\) is an arbitrary CCS\(_H\) term. We claim that:

**Claim 1** Each CCS\(_H\) term \(t\) is bisimilar to \(0\) if, and only if, \(t \in \text{NIL}\).

Using this claim and structural induction on \(t \in \text{NIL}\), it is a simple matter to show that if \(t \equiv 0\), then \(t \approx 0\) is provable using axioms A4, HM1 and M1 from left to right, which was to be shown.

To complete the proof, it therefore suffices to show the above claim. To establish the “if” implication in the statement of the claim, one proves, using structural induction on \(t\) and the congruence properties of bisimilarity (Fact 2.1), that if \(t \in \text{NIL}\), then \(\sigma(t) \equiv 0\) for every closed substitution \(\sigma\). To show the “only if” implication, we establish the contrapositive statement, viz. that if \(t \notin \text{NIL}\), then \(\sigma(t) \notin 0\) for some closed substitution \(\sigma\). To this end, it suffices only to show, using structural induction on \(t\), that if \(t \notin \text{NIL}\), then \(\sigma_a(t) \mid \mu\) for some action \(\mu \in \{a, \bar{a}, \tau\}\), where \(\sigma_a\) is the closed substitution mapping each variable to the closed term \(a0\). The details of this argument are not hard, and are therefore left to the reader.

In light of the above result, we find it convenient to make the following:

**Simplifying Assumption 3** In the technical developments to follow, we shall assume, without loss of generality, that each axiom system we consider includes the equations in Table 3.

This assumption means, in particular, that our axiom systems will allow us to identify each term that is bisimilar to \(0\) with \(0\).
In the remainder of this paper, process terms are considered modulo associativity and commutativity of +. In other words, we do not distinguish $t + u$ and $u + t$, nor $(t + u) + v$ and $t + (u + v)$. This is justified because, as previously observed, bisimulation equivalence satisfies axioms A1, A2 in Table 3. In what follows, the symbol $=\equiv$ will denote equality modulo axioms A1, A2. We use a summation $\sum_{i\in\{1,\ldots,k\}} t_i$ to denote $t_1 + \cdots + t_k$, where the empty sum represents 0. It is easy to see that, modulo the equations in Table 3, every CCS term $t$ has the form $\sum_{i\in I} t_i$, for some finite index set $I$, and terms $t_i (i \in I)$ that are not 0 and do not have themselves the form $t' + t''$, for some terms $t'$ and $t''$. The terms $t_i (i \in I)$ will be referred to as the summands of $t$. Moreover, again modulo the equations in Table 3 each of the $t_i$ can be assumed to have no 0 factors. (Recall that this means that, whenever a term of the form $t' \not\equiv 0$ or $t' \mid t''$ is a subterm of $t_i$, then $t' \not\equiv 0$ and $t'' \not\equiv 0$.) For example, a term of the form $\bar{a}0 \mid 0$ will not be considered a summand in what follows because, using equation M1 in Table 3, that term can be proven equal to $a0 + \bar{a}0$. The collection of summands of a term $t$ can be inductively characterized thus:

- 0 has no summands;
- $x$ and $\mu t$ are their only summands;
- $u$ is a summand of $t_1 + t_2$ if it is either a summand of $t_1$ or a summand of $t_2$;
- the summands of $t_1 \mid t_2$ are
  - those of $t_2$, if $t_1 \equiv 0$,
  - those of $t_1$, if $t_2 \equiv 0$, and
  - only $t_1 \mid t_2$, otherwise;
- the summands of $t_1 \not\equiv t_2$ are
  - none, if $t_1 \equiv 0$,
  - those of $t_1$, if $t_2 \equiv 0$, and
  - only $t_1 \not\equiv t_2$, otherwise.

It is well-known (cf., e.g., Sect. 2 in [19]) that if an equation relating two closed terms can be proven from an axiom system $E$, then there is a closed proof for it. We shall now argue that if $E$ satisfies a further closure property in addition to those mentioned earlier, and that closed equation relates two terms containing no occurrences of 0 as a summand or factor, then there is a closed proof for it in which all of the terms have no occurrences of 0 as a summand or factor—see [28, Proposition 5.1.5].

**Definition 2.9**
1. For CCS$_H$ terms $t$ and $t'$, we write $t \leadsto t'$ if $t'$ can be obtained from $t$ by applying one of the equations $A3$, $A4$, $HM1$, $HM2$, $M1$ and $M2$ from left to right. As usual, we write $\leadsto^*$ for the reflexive, transitive closure of the relation $\leadsto$.

2. Let $E$ be an axiom system. We define the axiom system $\text{cl}(E)$ thus:

$$\text{cl}(E) = \{ t' \approx u' \mid (t \approx u) \in E, t \leadsto^* t' \text{ and } u \leadsto^* u' \}.$$ 

3. An axiom system $E$ is saturated if $E = \text{cl}(E)$.

Intuitively, one application of the rewrite relation $\leadsto$ eliminates one occurrence of $0$ as a summand or a factor in terms. Note that $t \leadsto t'$ holds whenever $t \leadsto^* t'$.

The following lemma collects some basic sanity properties of the closure operator $\text{cl}(\cdot)$. (Note, in particular, that the application of $\text{cl}(\cdot)$ to an axiom system satisfying our simplifying assumptions is guaranteed to produce a saturated axiom system that also affords them.)

**Lemma 2.2** Let $E$ be an axiom system. Then the following statements hold.

1. $E \subseteq \text{cl}(E) = \text{cl}(\text{cl}(E))$.

2. $\text{cl}(E)$ is finite, if so is $E$.

3. $\text{cl}(E)$ is sound, if so is $E$.

4. $\text{cl}(E)$ is closed with respect to $0$ substitutions and symmetry, if so is $E$.

5. $\text{cl}(E)$ and $E$ prove the same equations, if $E$ contains the equations in Table 3.

**Proof:** We limit ourselves to sketching a proof of the second statement in the lemma. To prove this claim, we begin by noting that the size of the term $t'$ is smaller than that of $t$ whenever $t \leadsto t'$. Using this observation, it is not hard to see that, for each term $t$, the set

$$\{ t' \mid t \leadsto^* t' \}$$

is finite. In fact, the rooted tree with root $t$ resulting from the unfolding of the directed acyclic graph whose nodes are the terms reachable from $t$ via $\leadsto^*$, and whose edges are given by the $\leadsto$ relation is finitely branching, and all of its paths are finite because the $\leadsto$ relation decreases the size of terms. Thus this tree must be finite, or else it would have an infinite path by König’s lemma. It follows that, for each equation $t \approx u$ in $E$, the set $\text{cl}(E)$ contains $nm$ equations, where $n$ and $m$ are the cardinalities of the sets $\{ t' \mid t \leadsto^* t' \}$ and $\{ u' \mid u \leadsto^* u' \}$, respectively. We may therefore conclude that $\text{cl}(E)$ is finite, if so is $E$.

We now proceed to characterize syntactically the normal forms of the rewriting relation $\leadsto$. The syntactic characterization of the normal forms given below will be useful in obtaining the promised result to the effect that if a saturated axiom system
$E$ proves a closed equation relating two terms containing no occurrences of $0$ as a summand or factor, then there is a closed proof for it in which all of the terms have no occurrences of $0$ as a summand or factor.

**Definition 2.10** For each CCS$_H$ term $t$, we define $t/0$ thus:

- $0/0 = 0$
- $(t + u)/0 = \begin{cases} u/0 & \text{if } t \rightsquigarrow 0 \\ t/0 & \text{if } u \rightsquigarrow 0 \\ (t/0) + (u/0) & \text{otherwise} \end{cases}$
- $x/0 = x$
- $(t \n/ u)/0 = \begin{cases} 0 & \text{if } t \rightsquigarrow 0 \\ t/0 & \text{if } u \rightsquigarrow 0 \\ (t/0) \n (u/0) & \text{otherwise} \end{cases}$
- $\mu t/0 = \mu(t/0)$
- $(t \mid u)/0 = \begin{cases} u/0 & \text{if } t \rightsquigarrow 0 \\ t/0 & \text{if } u \rightsquigarrow 0 \\ (t/0) \mid (u/0) & \text{otherwise} \end{cases}$

Intuitively, $t/0$ is the term that results by removing all occurrences of $0$ as a summand or factor from $t$.

The following lemma, whose simple proof by structural induction on terms is omitted, collects the basic properties of the above construction. In particular, note that, as expected, the term $t/0$ is the normal form for $t$ with respect to the rewrite relation $\rightsquigarrow$.

**Lemma 2.3** For each CCS$_H$ term $t$, the following statements hold:

1. $t \rightsquigarrow^* t/0$ and therefore $t \rightsquigarrow t/0$;
2. $t/0 \rightsquigarrow u$ for no term $u$;
3. the term $t/0$ has no occurrence of $0$ as a summand or factor;
4. $t/0 = t$, if $t$ has no occurrence of $0$ as a summand or factor.

We are now ready to state our counterpart of [28, Proposition 5.1.5].

**Proposition 2.1** Assume that $E$ is a saturated axiom system. Suppose furthermore that we have a closed proof from $E$ of the closed equation $p \approx q$. Then replacing each term $r$ in that proof with $r/0$ yields a closed proof of the equation $p/0 \approx q/0$. In particular, the proof from $E$ of an equation $p \approx q$, where $p$ and $q$ are terms not containing occurrences of $0$ as a summand or factor, need not use terms containing occurrences of $0$ as a summand or factor.

**Proof:** The proof follows the lines of that of [28, Proposition 5.1.5], and is therefore omitted.
In light of this result, since the saturation of a finite axiom system that includes the equations in Table 3 results in an equivalent, finite collection of equations (Lemma 2.2(2) and (3)), we put forth our last:

**Simplifying Assumption 4** Henceforth, we shall limit ourselves to considering saturated axiom systems.

The use of saturated axiom systems will play an important role in the proof of our main technical results.

### 3 Hennessy’s Merge is not Finitely Based

Our order of business in the remainder of this paper will be to show the following result to the effect that bisimulation equivalence does not admit a finite equational axiomatization over the language $\text{CCS}_H$, and that thus Bergstra and Klop were indeed right in writing in [8, page 118] that:

“It seems that $\gamma$ does not have a finite equational axiomatization.”

(In op. cit. Bergstra and Klop used $\gamma$ to denote Hennessy’s merge.)

**Theorem 3.1** Bisimulation equivalence admits no finite equational axiomatization over the language $\text{CCS}_H$. In fact, the collection of closed equations over that language that hold with respect to bisimulation equivalence has no finite equational axiomatization.

As a first stepping stone towards the proof of this result, we now proceed to argue that it is sufficient to show that bisimulation equivalence admits no finite equational axiomatization over the language $\text{CCS}_H$ consisting of the $\text{CCS}_H$ terms that do not contain occurrences of the parallel composition operator. Even though this observation is not unexpected—as equation (2) essentially states that parallel composition is a derived operator in the algebra of $\text{CCS}_H$ terms modulo bisimulation equivalence—, we now argue for it in some detail for the sake of completeness.

**Definition 3.1** For each $\text{CCS}_H$ term $t$, we define $\hat{t}$ thus:

\[
\begin{align*}
\hat{0} &= 0 \\
\hat{x} &= x \\
\hat{\mu t} &= \mu \hat{t} \\
\hat{t + u} &= \hat{t} + \hat{u} \\
\hat{t \parallel u} &= \hat{t} \parallel \hat{u} \\
\hat{t | u} &= (\hat{t} \parallel \hat{u}) + (\hat{u} \parallel \hat{t})
\end{align*}
\]

If $E$ is an axiom system over the language $\text{CCS}_H$, then

\[\hat{E} = \{ \hat{t} \approx \hat{u} \mid (t \approx u) \in E \} .\]

Note that, for each $\text{CCS}_H$ term $t$, the term $\hat{t}$ is in the language $\text{CCS}_H$. Moreover, if $t$ contains no occurrences of the parallel composition operator, then $\hat{t} = t$. Since equation (2) is sound with respect to bisimulation equivalence, and bisimilarity is a congruence (Fact 2.1), it is not hard to show that:
Fact 3.1 Each term \( t \) in the language \( \text{CCS}_H \) is bisimilar to \( \hat{t} \). Therefore if \( E \) is an axiom system over the language \( \text{CCS}_H \) that is sound with respect to bisimilarity, then \( \hat{E} \) is an axiom system over the language \( \text{CCS}_H \) that is sound with respect to bisimilarity.

The following result states the promised reduction of the non-finite axiomatizability of bisimilarity over the language \( \text{CCS}_H \) to that of bisimilarity over the language \( \text{CCS}_H^- \).

Proposition 3.1 Let \( E \) be an axiom system over the language \( \text{CCS}_H \). Then the following statements hold.

1. If \( E \) proves the equation \( t \approx u \), then \( \hat{E} \) proves the equation \( \hat{t} \approx \hat{u} \).

2. If \( E \) gives a complete axiomatization of bisimulation equivalence over the language \( \text{CCS}_H \), then \( \hat{E} \) completely axiomatizes bisimulation equivalence over the language \( \text{CCS}_H^- \).

3. If bisimulation equivalence admits no finite equational axiomatization over the language \( \text{CCS}_H^- \), then it has no finite equational axiomatization over the language \( \text{CCS}_H \) either.

Proof: We prove the three statements separately.

- **Proof of Statement 1.** Assume that \( E \vdash t \approx u \). We shall argue that \( \hat{E} \) proves the equation \( \hat{t} \approx \hat{u} \) by induction on the depth of the proof of \( t \approx u \) from \( E \). We proceed by a case analysis on the last rule used in the proof. Below we only consider the two most interesting cases in this analysis.

  - **Case** \( E \vdash t \approx u \), **because** \( \sigma(t') = t \) **and** \( \sigma(u') = u \) **for some equation** \( (t' \approx u') \in E \). Note, first of all, that, by the definition of \( \hat{E} \), the equation \( \hat{t}' \approx \hat{u}' \) is contained in \( \hat{E} \). Observe now that
    
    \[
    \hat{t} = \hat{\sigma(t')} \text{ and } \hat{u} = \hat{\sigma(u')},
    \]

    where \( \hat{\sigma} \) is the substitution mapping each variable \( x \) to the term \( \sigma(x) \). It follows that the equation \( \hat{t} \approx \hat{u} \) can be proven from the axiom system \( \hat{E} \) by instantiating the equation \( \hat{t}' \approx \hat{u}' \) with the substitution \( \hat{\sigma} \), and we are done.

  - **Case** \( E \vdash t \approx u \), **because** \( t = t_1 \mid t_2 \) **and** \( u = u_1 \mid u_2 \) **for some** \( t_i, u_i \) (**\( i = 1, 2 \)**) **such that** \( E \vdash t_i \approx u_i \) (**\( i = 1, 2 \)**). Using the inductive hypothesis twice, we have that \( \hat{E} \vdash \hat{t}_i \approx \hat{u}_i \) (**\( i = 1, 2 \)**). Therefore, using substitutivity, \( \hat{E} \) proves that
    
    \[
    \hat{t} = (\hat{t}_1 \upharpoonright \hat{t}_2) + (\hat{t}_2 \upharpoonright \hat{t}_1) \approx (\hat{u}_1 \upharpoonright \hat{u}_2) + (\hat{u}_2 \upharpoonright \hat{u}_1) = \hat{u},
    \]

    which was to be shown.
The remaining cases are simpler, and we leave the details to the reader.

**Proof of Statement** Assume that \( t \) and \( u \) are two bisimilar terms in the language \( \text{CCS}_H \). We shall argue that \( \hat{E} \) proves the equation \( t \approx u \). To this end, we begin by noting that the equation \( t \approx u \) also holds in the algebra of \( \text{CCS}_H \) terms modulo bisimulation. In fact, for each term \( v \) in the language \( \text{CCS}_H \) and closed substitution \( \sigma \) mapping variables to \( \text{CCS}_H \) terms, we have that

\[
\sigma(v) \leftrightarrow \tilde{\sigma}(v) ,
\]

where the substitution \( \tilde{\sigma} \) is defined as above.

Since \( E \) is complete for bisimilarity over \( \text{CCS}_H \) by our assumptions, it follows that \( \hat{E} \) proves the equation \( t \approx u \). Therefore, by statement 1 of the proposition, we have that \( \hat{E} \) proves the equation \( \hat{t} \approx \hat{u} \). The claim now follows because \( \hat{t} = t \) and \( \hat{u} = u \).

**Proof of Statement** This is an immediate consequence of statement 2 because \( \hat{E} \) has the same cardinality of \( E \), and is therefore finite, if so is \( E \).

In light of this result, henceforth we shall focus on proving that bisimulation equivalence affords no finite equational axiomatization over the language \( \text{CCS}_H \). The following infinite family of closed \( \text{CCS}_H \) terms will play a key role in the technical developments to follow:

\[
e_n : \ a0 \not\vdash p_n \approx ap_n + \sum_{i=0}^{n} \tau a^i \ (n \geq 0) , \tag{3}
\]

where the terms \( p_n \) are defined thus:

\[
p_n = \sum_{i=0}^{n} \bar{a} a^i \ (n \geq 0) .
\]

It is not hard to see that all of the equations \( e_n \ (n \geq 0) \) are sound modulo bisimulation. In the remainder of this paper, we shall prove the following result, of which Theorem 3.1 is an immediate consequence, to the effect that no finite collection of equations over the language \( \text{CCS}_H \) that are sound with respect to bisimulation equivalence can prove all of the equations \( e_n \ (n \geq 0) \).

**Theorem 3.2** Let \( E \) be a finite axiom system over the language \( \text{CCS}_H \) that is sound with respect to bisimulation equivalence. Let \( n \) be larger than the size of each term in the equations in \( E \). Then \( E \) does not prove the sound equation \( e_n \) from (3).
The remainder of this paper will be devoted to a proof of the above result, which will be given along proof theoretic lines that have their roots in Moller’s arguments to the effect that bisimulation equivalence is not finitely based over the language CCS—see the references [28][29][30]. More precisely, to establish Theorem 3.2 we shall show that there is a property of terms associated with each finite axiom system $E$ over the language $\text{CCS}_H$ that is sound with respect to bisimulation equivalence, such that whenever the equation $p \approx q$ can be derived from $E$, for some “suitably large” closed terms without 0 summands and factors, then either both $p$ and $q$ enjoy the property, or none of them does. The aforementioned property must be chosen so that, for suitably large values of $n$, the right-hand side of equality $e_n$, viz. the term $a0 \not\parallel p_n$, affords it, whilst the left-hand side, viz. the term $ap_n + \sum_{i=0}^{n} \tau a^i$, does not.

**Remark 3.1** In the absence of synchronization, Hennessy’s merge reduces to the left merge operator of Bergstra and Klop’s. It follows that the collection of closed equations that hold modulo $\rightarrow$ over the sub-language of $\text{CCS}_H$ obtained by considering those terms that do not contain occurrences of the $\bar{a}$ prefixing operator has a finite equational axiomatization. Therefore the use of synchronization is necessary in the proof of Theorem 3.1.

The following proposition states the property mentioned in the proof strategy outlined above.

**Proposition 3.2** Let $E$ be a finite axiom system over the language $\text{CCS}_H$ that is sound with respect to bisimulation equivalence. Let $n$ be larger than the size of each term in the equations in $E$. Assume that $p$ and $q$ are closed terms that are bisimilar to $a0 \not\parallel p_n$, and contain no occurrences of 0 as a summand or a factor. If $E \vdash p \approx q$ and $p$ has a summand bisimilar to $a0 \not\parallel p_n$, then so does $q$.

Using the above proposition, it is a simple matter to prove Theorem 3.2. In fact, since none of the summands of the term $ap_n + \sum_{i=0}^{n} \tau a^i$, viz. $ap_n$ and $\tau a^i$ ($i \in \{0, \ldots, n\}$), is bisimilar to $a0 \not\parallel p_n$, if $n \geq 1$, Proposition 3.2 yields that the sound equality $e_n$ cannot be proven from $E$, and thus that $E$ is incomplete.

We shall now begin to develop the technical machinery that will be brought to bear in the proof of Proposition 3.2. This proof will occupy the remainder of this study.

## 4 Preparatory Results and Observations

Note that terms in the language $\text{CCS}_H$ may contain some occurrences of variables that can never contribute to the behaviour of their closed instantiations. A typical example of this situation occurs in the term $0 \not\parallel x$, which is bisimilar to 0.
However, terms that have no 0 factors contain no such redundant occurrences of variables. Moreover, each variable occurring in such terms contributes to the behaviour of its closed substantial instantiations. The following basic result, that will be used repeatedly in the technical developments to follow, formalizes this intuition.

**Lemma 4.1** Let $t$ be a CCS $H$ term, and let $\sigma$ be a closed substitution.

1. Assume that $t$ is not bisimilar to 0, and $\sigma$ is substantial. Then $\text{depth}(\sigma(t))$ is positive, and thus $\sigma(t) \not\rightarrow^* 0$.

2. If $t$ has no 0 factors and $x \in \text{var}(t)$, then $\text{depth}(\sigma(t)) \geq \text{depth}(\sigma(x))$.

**Remark 4.1** The requirement that $\sigma$ be substantial is necessary in statement 1 of the above lemma. For example, $x \not\rightarrow^* 0$, but $\sigma(x) \not\rightarrow 0$ if $\text{depth}(\sigma(x)) = 0$.

Similarly, the proviso that $t$ has no 0 factors cannot be omitted in statement 2. For instance, if $t = 0 \not\rightarrow^* x$ and $\sigma(x) = a0$, then $\text{depth}(\sigma(t)) < \text{depth}(\sigma(x))$.

In the proof of our main result, we shall make use of some notions from [27, 28]. These we now proceed to introduce for the sake of completeness and readability.

**Definition 4.1** A closed term $p$ is irreducible if $p \equiv q | r$ implies $q \equiv 0$ or $r \equiv 0$, for all closed terms $q, r$.

We say that $p$ is prime if it is irreducible and is not bisimilar to 0.

For example, each term $p$ of depth 1 is prime because every term of the form $q | r$ that does not involve 0 factors has depth at least 2, and thus cannot be bisimilar to $p$. The following proposition states the primality of two families of closed terms that will play a key role in the proof of our main result.

**Proposition 4.1**

1. Let $m \geq 1$ and $0 \leq i_1 < \ldots < i_m$. Then the term $\bar{a}.a^{i_1} + \cdots + \bar{a}.a^{i_m}$ is prime. In particular, $p_n$ is prime, for each $n \geq 1$.

2. The term $a0 \not\rightarrow^* p_n$ is prime, for each $n \geq 0$.

**Proof:** We prove the two claims separately. In each case, since $\bar{a}.a^{i_1} + \cdots + \bar{a}.a^{i_m}$ and $a0 \not\rightarrow^* p_n$ are not bisimilar to 0, it suffices only to show that the relevant term is irreducible.

- **Proof of Claim [1]** Suppose, towards a contradiction, that there exist closed terms $q, r$ that are not bisimilar 0 such that

  $\bar{a}.a^{i_1} + \cdots + \bar{a}.a^{i_m} \equiv q | r$.

  Then, since $q, r \not\rightarrow^* 0$, in light of the above equivalence we have that $q \rightarrow^* q'$ and $r \rightarrow^* r'$, for some $q', r'$. But then it follows that

  $q | r \rightarrow^* q' | r \rightarrow^* q' | r'$,
whereas the term \( \bar{a}.a^{i_1} + \cdots + \bar{a}.a^{i_m} \) cannot perform two subsequent \( \bar{a} \)-transitions. It follows that such \( q \) and \( r \) cannot exist, and hence that the term \( \bar{a}.a^{i_1} + \cdots + \bar{a}.a^{i_m} \) is irreducible, which was to be shown.

- **Proof of Claim** We now proceed to prove that \( a0 \not\leftrightarrow p_n \) is irreducible for \( n \geq 0 \).

  If \( n = 0 \) then \( a0 \not\leftrightarrow p_0 = a0 \not\leftrightarrow 0 \) is a term of depth 1, and is therefore irreducible as claimed.

  Let \( n \geq 1 \). Assume, towards a contradiction, that \( a0 \not\leftrightarrow p_n \not\leftrightarrow 0 \) for two closed terms \( p \) and \( q \) with \( p \neq 0 \) and \( q \neq 0 \)—that is, \( a0 \not\leftrightarrow p_n \) is not irreducible. Since \( n \geq 1 \), we have that

  \[
  a0 \not\leftrightarrow p_n \not\xrightarrow{\tau} 0 \not\leftrightarrow 0 .
  \]

  As \( a0 \not\leftrightarrow p_n \not\xrightarrow{\tau} 0 \), there is a transition \( p \not\xrightarrow{\tau} 0 \), for some \( p \), \( q \) with \( p \neq 0 \) and \( q \neq 0 \), the transition \( p \not\xrightarrow{\tau} 0 \), \( q \not\xrightarrow{\tau} 0 \) must be derived from the synchronization of two transitions \( p \not\xrightarrow{\tau} 0 \) and \( q \not\xrightarrow{\tau} 0 \) with \( \alpha \in \{a, \bar{a}\} \). This means that \( p \not\xrightarrow{\alpha} q \), contradicting the assumption that \( a0 \not\leftrightarrow p_n \not\xrightarrow{\tau} 0 \). Thus \( a0 \not\leftrightarrow p_n \) is irreducible, which was to be shown.

\[\square\]

**Lemma 4.2** Let \( t \) be a term in the language \( \text{CCS}_H \) with neither 0 summands nor factors that does not have + as head operator. Assume that \( \sigma \) is a closed substantial substitution, and that

\[
\sigma(t) \not\xrightarrow{\tau} a.a^{i_1} + \cdots + \bar{a}.a^{i_m} ,
\]

for some \( m \geq 1 \) and \( 0 \leq i_1 < \ldots < i_m \). Then \( t = x \), for some variable \( x \).

**Proof:** Assume, towards a contradiction, that \( t \) is not a variable. We proceed by a case analysis on the possible form this term may have.

1. **Case** \( t = \mu t' \) **for some term** \( t' \). Then \( \mu = \bar{a} \) and \( a^{i_1} \not\xrightarrow{\tau} a^{i_m} \).

   However, this is a contradiction because, since \( i_1 \neq i_m \), the terms \( a^{i_1} \) and \( a^{i_m} \) are not bisimilar.

2. **Case** \( t = t' \not\leftrightarrow t'' \) **for some terms** \( t', t'' \). Since \( t \) has no 0 factors, we have that neither \( t' \) nor \( t'' \) is bisimilar to 0. As \( \sigma \) is a substantial substitution, it follows that \( \sigma(t') \not\xrightarrow{\tau} 0 \) and \( \sigma(t'') \not\xrightarrow{\tau} 0 \).

   Observe now that \( \bar{a}.a^{i_1} + \cdots + \bar{a}.a^{i_m} \not\xrightarrow{\tau} a^{i_m} \). Thus, as

   \[
   \sigma(t) = \sigma(t') \not\leftrightarrow \sigma(t'') \not\xrightarrow{\tau} a.a^{i_1} + \cdots + \bar{a}.a^{i_m} ,
   \]

   there is a term \( p \) such that

   \[
   \sigma(t') \not\xrightarrow{\alpha} p \text{ and } p \not\xrightarrow{\tau} \sigma(t'') \not\xrightarrow{\tau} a^{i_m} .
   \]

20
As \( \sigma(t'') \not\stackrel{\sim}{\rightarrow} 0 \), this implies that \( \sigma(t'') \not\rightarrow q \), for some \( q \). This leads to a contradiction, because the term \( \sigma(t) = \sigma(t') \not\rightarrow \sigma(t'') \) affords an initial \( \tau \)-transition, viz.

\[
\sigma(t) = \sigma(t') \not\rightarrow \sigma(t'') \rightarrow p \mid q ,
\]

whereas \( \bar{a}a^1 + \cdots + \bar{a}a^m \) does not.

We may therefore conclude that \( t \) must be a variable, which was to be shown. \( \square \)

The following decomposition property will find application in the proof of our main technical result, viz. Proposition 5.1 to follow.

**Lemma 4.3** Let \( n \geq 1 \). Assume that \( p \not\rightarrow q \leftrightarrow a0 \not\rightarrow p_n \), where \( q \) is a closed term that is not bisimilar to \( 0 \). Then \( p \leftrightarrow a0 \) and \( q \leftrightarrow p_n \).

**Proof:** Since \( p \not\rightarrow q \leftrightarrow a0 \not\rightarrow p_n \) and \( a0 \not\rightarrow p_n \), there is a \( p' \) such that \( p \rightarrow p' \) and \( p' \not\rightarrow 0 \). It follows that \( q \not\leftrightarrow 0 \), because \( p_n \) is prime (Proposition 4.1) and \( q \not\rightarrow 0 \). We are therefore left to prove that \( p \) is bisimilar to \( a0 \). To this end, note, first of all, that, as \( \leftrightarrow \) is a congruence over the language \( \text{CCS}_H \), we have that

\[
p \not\leftrightarrow p_n \leftrightarrow a0 \not\leftrightarrow p_n .
\]

Assume now that \( p \not\rightarrow p'' \) for some action \( \mu \) and closed term \( p'' \). In light of the above equivalence, one of the following two cases may arise:

1. \( \mu = a \) and \( p'' \not\rightarrow p_n \) or
2. \( \mu = \tau \) and \( p'' \not\rightarrow a^i \), for some \( i \in \{0, \ldots, n\} \).

In the former case, \( p'' \) must have depth \( 0 \) and is thus bisimilar to \( 0 \). The latter case is impossible, because the depth of \( p'' \not\rightarrow p_n \) is at least \( n + 1 \).

We may therefore conclude that every transition of \( p \) is of the form \( p \rightarrow p'' \), for some \( p'' \not\rightarrow 0 \). Since we have already seen that \( p \) affords an \( a \)-labelled transition leading to \( 0 \), modulo bisimulation equivalence, it follows that \( p \leftrightarrow a0 \), which was to be shown. \( \square \)

**Lemma 4.4** Let \( t \approx u \) be an equation over the language \( \text{CCS}_H \) that is sound with respect to bisimulation equivalence, where \( t \) and \( u \) are terms that have neither \( 0 \) summands nor factors. Assume that some variable \( x \) occurs as a summand in \( t \). Then \( x \) also occurs as a summand in \( u \).

**Proof:** Recall that, for some finite index sets \( I, J \), we can write

\[
t = \sum_{i \in I} t_i \tag{4}
\]

\[
u = \sum_{j \in J} u_j , \tag{5}
\]

21
where none of the \( t_i (i \in I) \) and \( u_j (j \in J) \) is 0 or a sum. Assume that variable \( x \) occurs as a summand in \( t \)—i.e., that there is an \( i \in I \) with \( t_i = x \). We shall argue that \( x \) also occurs as a summand in \( u \)—i.e., that there is a \( j \in J \) with \( u_j = x \).

Consider the substitution \( \sigma_0 \) mapping each variable to 0. Pick an integer \( m \) larger than the depth of \( \sigma_0(t) \) and of \( \sigma_0(u) \). Let \( \sigma \) be the substitution mapping \( x \) to the term \( a^{m+1} \) and agreeing with \( \sigma_0 \) on all the other variables.

As \( t \approx u \) is sound with respect to bisimulation equivalence, we have that
\[
\sigma(t) \leftrightarrow \sigma(u).
\]
Moreover, the term \( \sigma(t) \) affords the transition \( \sigma(t) \xrightarrow{a} a^m \), for \( t_i = x \) and \( \sigma(x) = a^{m+1} \xrightarrow{a} a^m \). Hence, for some closed term \( p \),
\[
\sigma(u) = \sum_{j \in J} \sigma(u_j) \xrightarrow{a} p \xrightarrow{a} a^m.
\]
This means that there is a \( j \in J \) such that \( \sigma(u_j) \xrightarrow{a} p \). We claim that this \( u_j \) can only be the variable \( x \). To see that this claim holds, observe, first of all, that \( x \in \text{var}(u_j) \). In fact, if \( x \) did not occur in \( u_j \), then we would reach a contradiction thus:
\[
m = \text{depth}(p) < \text{depth}(\sigma(u_j)) = \text{depth}(\sigma_0(u_j)) \leq \text{depth}(\sigma_0(u)) < m.
\]
Using this observation and Lemma 4.1(2), it is not hard to show that, for each of the other possible forms \( u_j \) may have, \( \sigma(u_j) \) does not afford an \( a \)-labelled transition leading to a term of depth \( m \). We may therefore conclude that \( u_j = x \), which was to be shown.

5 Proof of Proposition 3.2

We now proceed to present a detailed proof of Proposition 3.2. The following result, stating that the property mentioned in the statement of that proposition holds for all closed substantial instantiations of axioms in \( E \), will be the crux in such a proof.

**Proposition 5.1** Let \( t \approx u \) be an equation over the language \( \text{CCS}_{\mu} \) that is sound with respect to bisimulation equivalence, where \( t \) and \( u \) are terms without 0 summands or factors. Let \( n \) be larger than the size of \( t \). Assume that \( \sigma \) is a substantial substitution. Let \( p = \sigma(t) \) and \( q = \sigma(u) \). Suppose that \( p \) and \( q \) are bisimilar to \( a0 \not\| p_n \). If \( p \) has a summand bisimilar to \( a0 \not\| p_n \), then so does \( q \).

**Proof:** We can assume that, for some finite non-empty index sets \( I, J \),
\[
t = \sum_{i \in I} t_i \quad \text{and} \quad u = \sum_{j \in J} u_j.
\]

22
where none of the \( t_i \) \((i \in I)\) and \( u_j \) \((j \in J)\) is 0 or a sum. (That is, none of the \( t_i \) \((i \in I)\) and \( u_j \) \((j \in J)\) has + as its head operator.) Note that, as \( t \) and \( u \) have no 0 summands or factors, then none of the \( t_i \) \((i \in I)\) and \( u_j \) \((j \in J)\) does either.

Since \( p = \sigma(t) \) has a summand bisimilar to \( a0 \not\| p_n \), there is an index \( i \in I \) such that
\[
\sigma(t_i) \leftrightarrow a0 \not\| p_n .
\]
Our aim is now to show that there is an index \( j \in J \) such that
\[
\sigma(u_j) \leftrightarrow a0 \not\| p_n ,
\]
proving that \( q = \sigma(u) \) also has a summand bisimilar to \( a0 \not\| p_n \). This we proceed to do by a case analysis on the form \( t_i \) may have.

1. **Case** \( t_i = x \) **for some variable** \( x \). In this case, we have that
\[
\sigma(x) \leftrightarrow a0 \not\| p_n ,
\]
and \( t \) has \( x \) as a summand. As \( t \approx u \) is sound with respect to bisimulation equivalence and neither \( t \) nor \( u \) have 0 summands or factors, it follows that \( u \) also has \( x \) as a summand (Lemma 4.4). Thus there is an index \( j \in J \) such that \( u_j = x \), and, modulo bisimulation, \( \sigma(u) \) has \( a0 \not\| p_n \) as a summand, which was to be shown.

2. **Case** \( t_i = \mu t' \) **for some term** \( t' \). This case is vacuous because, since
\[
\sigma(t_i) = \mu \sigma(t') \xrightarrow{\mu} \sigma(t')
\]
is the only transition afforded by \( \sigma(t_i) \), this term cannot be bisimilar to \( a0 \not\| p_n \).

3. **Case** \( t_i = t' \not\| t'' \) **for some terms** \( t', t'' \). The analysis of this case is the crux of the proof, and we present the argument in considerable detail.

Since \( t_i = t' \not\| t'' \), we have that
\[
\sigma(t_i) = \sigma(t') \not\| \sigma(t'') \leftrightarrow a0 \not\| p_n .
\]
As \( \sigma \) is a substantial substitution, it follows that \( \sigma(t') \not\leftrightarrow 0 \) and \( \sigma(t'') \not\leftrightarrow 0 \) (Lemma 4.3). Thus \( \sigma(t') \leftrightarrow a0 \) and \( \sigma(t'') \leftrightarrow p_n \) (Lemma 4.3). Now, \( t'' \) can be written thus:
\[
t'' = v_1 + \cdots + v_\ell \quad (\ell > 0) ,
\]
where none of the summands \( v_i \) is 0 or a sum. Observe that, since \( n \) is larger than the size of \( t \), we have that \( \ell < n \). Hence, since
\[
\sigma(t'') \leftrightarrow p_n = \sum_{i=0}^{n} \bar{a}a^i ,
\]
23
there must be some $h \in \{1, \ldots, \ell\}$ such that
\[ \sigma(v_h) \leftrightarrow \bar{a}.a^{i_1} + \cdots + \bar{a}.a^{i_m} \]
for some $m > 1$ and $0 \leq i_1 < \ldots < i_m \leq n$. By Lemma 4.2, it follows that
\[ v_h \] can only be a variable $x$ and thus that
\[ \sigma(x) \leftrightarrow \bar{a}.a^{i_1} + \cdots + \bar{a}.a^{i_m}. \quad (8) \]
Since $t'$ has no $0$ factors, the above equation yields that $x \not\in \text{var}(t')$—or else
\[ \sigma(t') \not\leftrightarrow a0 \text{ (Lemma 4.1(2)).} \]
Thus, since $\sigma$ is substantial, modulo bisimulation equivalence,
\[ t' = y_1 + \cdots + y_k[+a0] \quad (9) \]
for some $k \geq 0$ and some variables $y_1, \ldots, y_k$ different from $x$ with
\[ \sigma(y_1) \leftrightarrow \cdots \sigma(y_k) \leftrightarrow a0. \]
(The notation $[+a0]$ in (9) denotes an optional $a0$ summand. Moreover, if $k = 0$, then $t' = a0$.) So, modulo bisimulation equivalence, \[ t_i \rightarrow p' \leftrightarrow a0 \not\vdash p_n \]
for some $p'$ also holds. Since $t \approx u$ is sound with respect to $\leftrightarrow$, it follows that
\[ t_i \rightarrow \sigma' \leftrightarrow a0 \not\vdash p_n. \]
Recall that, by one of the assumptions of the proposition, \[ \sigma(u) \not\leftrightarrow a0 \not\vdash p_n, \]
and thus $\sigma(u)$ has depth $n + 2$. On the other hand, by (10), $\text{depth}(\sigma'(u_j)) \geq n + 3$. Since $\sigma$ and $\sigma'$ differ only in the closed term they map variable $x$ to, it follows that
\[ x \in \text{var}(u_j). \quad (11) \]
We now proceed to show that $\sigma(u_j) \not\leftrightarrow a0 \not\vdash p_n$ by a further case analysis on the form a term $u_j$ satisfying (10) and (11) may have.
These are our proof by examining the two possible origins for transition (10).

(a) Case \( u_j = x \). This case is vacuous because \( \sigma'(x) = \bar{a}(a0 \not \vdash p_n) \vdash \), and thus this possible form for \( u_j \) does not meet (10).

(b) Case \( u_j = \mu u' \) for some term \( u' \). In light of (10), we have that \( \mu = \tau \) and \( q' = \sigma'(u') \vdash (a0 \not \vdash p_n) \). Using (11) and the fact that \( u' \) has no 0 factors, we have that \( \text{depth}(\sigma'(u')) \geq n + 3 \) (Lemma 4.1(2)). Since \( a0 \not \vdash p_n \) has depth \( n+2 \), this contradicts the fact that \( \sigma'(u') \vdash a0 \not \vdash p_n \).

(c) Case \( u_j = u' \not \vdash u'' \) for some terms \( u', u'' \). This is the lengthiest sub-case of case 3 of the proof, and its analysis will occupy us for the next couple of pages.

Our assumption that \( u \) has no 0 factors yields that neither \( u' \) nor \( u'' \) is bisimilar to 0. Moreover, by (11), either \( x \in \text{var}(u') \) or \( x \in \text{var}(u'') \).

Since \( \sigma'(u_j) = \sigma'(u') \not \vdash \sigma'(u'') \) affords transition (10), we have that \( q' = q_1 \not \vdash q_2 \) for some \( q_1, q_2 \). Since \( a0 \not \vdash p_n \) is prime (Proposition 4.1(2)), it follows that either \( q_1 \vdash 0 \) or \( q_2 \vdash 0 \). We now continue our proof by examining the two possible origins for transition (10). These are

1. \( \sigma'(u') \vdash q_1 \) and \( q_2 = \sigma'(u'') \) and
2. \( \sigma'(u') \vdash q_1 \) and \( \sigma'(u'') \vdash q_2 \), with \( \alpha \in \{a, \bar{a}\} \).

We examine these two cases in turn.

i. Assume that \( \sigma'(u') \vdash q_1 \) and \( q_2 = \sigma'(u'') \). We now proceed to argue that this case produces a contradiction. To this end, note first of all that, as \( \sigma' \) is substantial and \( u'' \) is not bisimilar to 0, it must be the case that \( q_1 \vdash 0 \) and \( q_2 = \sigma'(u'') \vdash a0 \not \vdash p_n \). In light of the definition of \( \sigma' \), it follows that \( x \) occurs in \( u' \), but not in \( u'' \) (Lemma 4.1(2)). Therefore, since \( \sigma \) and \( \sigma' \) only differ at the variable \( x \),

\[
\sigma(u'') = \sigma'(u'') \vdash a0 \not \vdash p_n .
\]

Since \( \vdash \) is a congruence, we derive that

\[
\sigma(u_j) = \sigma(u') \not \vdash \sigma(u'') \vdash \sigma(u') \not \vdash (a0 \not \vdash p_n) . \quad (12)
\]

Since \( \sigma \) is substantial, \( x \) occurs in \( u' \), and \( u' \) has no 0 factors, we may infer that

\[
n + 2 = \text{depth}(a0 \not \vdash p_n) = \text{depth}(\sigma(u)) \quad (\text{As } \sigma(u) \vdash a0 \not \vdash p_n) \\
\geq \text{depth}(\sigma(u_j)) \quad (\text{By (7)}) \\
= \text{depth}(\sigma(u')) + n + 2 \quad (\text{By (12)}) \\
> n + 2 \quad (\text{As } \text{depth}(\sigma(u')) > 0 \text{ by Lemma 4.1(2)}) ,
\]

which is the desired contradiction.
ii. Assume now that $\sigma'(u') \overset{\alpha}{\rightarrow} q_1$ and $\sigma'(u'') \overset{\bar{\alpha}}{\rightarrow} q_2$, with $\alpha \in \{a, \bar{a}\}$. Recall that exactly one of $q_1, q_2$ is bisimilar to 0. We proceed with the proof by considering these two possible cases in turn.

CASE $q_1 \nmid 0$. Our order of business will be to argue that, in this case, $\sigma(u_j) \nmid a0 \nmid p_n$, and thus that $q = \sigma(u)$ has a summand bisimilar to $a0 \nmid p_n$.

To this end, observe, first of all, that $q_2 \nmid a0 \nmid p_n$ by (10). It follows that $x \in \text{var}(u'')$, for otherwise we could derive a contradiction thus:

$$\text{depth}(a0 \nmid p_n) = \text{depth}(\sigma(u)) \quad (\text{As } \sigma(u) \nmid a0 \nmid p_n)$$
$$\geq \text{depth}(\sigma(u_j)) \quad (\text{By (7)})$$
$$> \text{depth}(\sigma(u'')) \quad (\text{As depth}(\sigma(u')) > 0)$$
$$> \text{depth}(\sigma'(u'')) \quad (\text{As } x \notin \text{var}(u''))$$
$$> \text{depth}(a0 \nmid p_n)$$

$$\quad (\text{As } \sigma'(u'') \overset{\bar{\alpha}}{\rightarrow} q_2 \nmid a0 \nmid p_n).$$

Moreover, we claim that $x \notin \text{var}(u')$. Indeed, if $x$ also occurred in $u'$, then, since $u'$ has no 0 factors, the term $\sigma(x)$ would contribute to the behaviour of $\sigma(u_j)$. Therefore, by (3), the term $\sigma(u_j)$ would afford a sequence of actions containing two occurrences of $\bar{a}$, contradicting our assumption that $\sigma(u) \nmid a0 \nmid p_n$. It follows that $\alpha = a$, because

$$\sigma'(u') = \sigma(u') \overset{\bar{\alpha}}{\rightarrow},$$

since $\sigma(u) \nmid a0 \nmid p_n$.

Observe now that, as $\sigma'(u'') \overset{\bar{\alpha}}{\rightarrow} q_2 \nmid a0 \nmid p_n$, it must be the case that $u''$ has a summand $x$. To see that this does hold, we examine the other possible forms a summand $w$ of $u''$ responsible for the transition

$$\sigma'(u'') \overset{\bar{\alpha}}{\rightarrow} q_2 \nmid a0 \nmid p_n,$$

may have, and argue that each of them leads to a contradiction.

A. CASE $w = \bar{a}w'$, FOR SOME TERM $w'$. In this case, $q_2 = \sigma'(w')$. However, the depth of such a $q_2$ is either smaller than $n + 2$ (if $x \notin \text{var}(w')$), or larger than $n + 2$ (if $x \in \text{var}(w')$). This contradicts the fact that $q_2$ is bisimilar to $a0 \nmid p_n$, because the latter term has depth $n + 2$.

B. CASE $w = w_1 \nmid w_2$, FOR SOME TERMS $w_1$ AND $w_2$. Since

$$\sigma'(w) = \sigma'(w_1) \nmid \sigma'(w_2) \overset{\bar{\alpha}}{\rightarrow} q_2,$$

there is a closed term $q_3$ such that $\sigma'(w_2) \overset{\bar{\alpha}}{\rightarrow} q_3$ and $q_2 = q_3 \mid \sigma'(w_2) \nmid a0 \nmid p_n$. As the term $a0 \nmid p_n$ is prime, $\sigma'$
is substantial, and $w_2$ is not bisimilar to $0$, we may infer that $q_3 \leftrightarrow 0$ and
\[ \sigma'(w_2) \equiv a0 \upharpoonright p_n. \]
It follows that $x \not\in \text{var}(w_2)$—or else the depth of $\sigma'(w_2)$ would be at least $n + 3$—, and therefore that
\[ \sigma'(w_2) = \sigma(w_2) \equiv a0 \upharpoonright p_n. \]
However, this contradicts our assumption that $\sigma(u) \equiv a0 \not\upharpoonright p_n$.

Summing up, we have argued that $u''$ has a summand $x$. Therefore, by (8),
\[ \sigma(u'') \equiv \bar{a}a^{i_1} + \cdots + \bar{a}a^{i_m} + r'', \]
for some closed term $r''$. We have already noted that
\[ \sigma(u') = \sigma'(u') \overset{a}{\rightarrow} q_1 \leftrightarrow 0. \]
Therefore, we have that
\[ \sigma(u') \equiv a0 + r', \]
for some closed term $r'$. Using the congruence properties of bisimulation equivalence, we may infer that
\[ \sigma(u_j) = \sigma(u') \not\equiv (a0 + r') \equiv (\bar{a}a^{i_1} + \cdots + \bar{a}a^{i_m} + r''). \]
In light of this equivalence, we have that
\[ \sigma(u_j) \overset{a}{\rightarrow} r \equiv \bar{a}a^{i_1} + \cdots + \bar{a}a^{i_m} + r'' \equiv \sigma(u'') \]
for some closed term $r$. By (7),
\[ q = \sigma(u) \overset{a}{\rightarrow} r. \]
Since $q = \sigma(u) \equiv a0 \not\upharpoonright p_n$ by our assumption, it must be the case that $r \equiv \sigma(u'') \not\equiv p_n$. So, again using the congruence properties of $\equiv$, we have that
\[ \sigma(u_j) = \sigma(u') \not\equiv (a0 + r') \not\equiv p_n. \]
As $\sigma(u) \equiv a0 \not\equiv p_n$, using Lemma 4.3 it is now a simple matter to infer that
\[ \sigma(u') \equiv a0. \]
Hence $\sigma(u_j) \equiv a0 \not\equiv p_n$. Note that $\sigma(u_j)$ is a summand of $q = \sigma(u)$. Therefore $q$ has a summand bisimilar to $a0 \not\equiv p_n$, which was to be shown.
CASE $q_2 \leftrightarrow 0$. We now proceed to argue that this case produces a contradiction. To this end, observe, first of all, that $q_1 \leftrightarrow a0 \not\vdash p_n$. Reasoning as in the analysis of the previous case, we may infer that $\alpha = a$, $x$ occurs in $u'$, but $x$ does not occur in $u''$. Moreover, since $\sigma'(u') \overset{a}{\rightarrow} q_1 \leftrightarrow a0 \not\vdash p_n$, it must be the case that $u' \overset{a}{\rightarrow} u'''$ for some $u'''$ such that

$$\sigma'(u'''') = q_1 \leftrightarrow a0 \not\vdash p_n.$$  

(For, otherwise, using Lemma 2.1(3), we would have that $\sigma'(u') \overset{a}{\rightarrow} q_1$ because $u' \overset{y}{\rightarrow} c$, $\sigma(y) \overset{a}{\rightarrow} q'_1$ and $q_1 = \sigma'[y_d \mapsto q'_1(c)]$, for some variable $y$, configuration $c$ and closed term $q'_1$. Note that $y \neq x$. In fact, if $y = x$, then we would have that $a = \bar{a}$ by the definition of $\sigma'$, contradicting the distinctness of these two complementary actions. Observe now that, again in light of the definition of $\sigma'$, the variable $x$ cannot occur in $c$, or else the depth of $q_1 = \sigma'[y_d \mapsto q'_1(c)]$ would be at least $n + 3$, contradicting our assumption that $q_1 \leftrightarrow a0 \not\vdash p_n$. Hence, since the variable $y$ is different from $x$, it is not hard to see that $\sigma(u') \overset{a}{\rightarrow} q_1$ also holds, and thus that $\text{depth}(q_1) < \text{depth}(\sigma(u)) = n + 2$, contradicting our assumption that $q_1 \leftrightarrow a0 \not\vdash p_n$.) Since $u$ contains no 0 factors, in light of the definition of $\sigma'$, this $u'''$ cannot contain occurrences of the variable $x$. (For, otherwise, Lemma 4.1(2) would yield that

$$\text{depth}(\sigma'(u''')) = \text{depth}(q_1) \geq n + 3,$$

contradicting our assumption that $q_1 \leftrightarrow a0 \not\vdash p_n$.) So

$$\sigma(u'''') = q_1 \leftrightarrow a0 \not\vdash p_n$$

also holds. Thus

\[
\begin{align*}
n + 2 &= \text{depth}(a0 \not\vdash p_n) \\
&= \text{depth}(\sigma(u)) \quad (\text{As } \sigma(u) \leftrightarrow a0 \not\vdash p_n) \\
&\geq \text{depth}(\sigma(u_j)) \quad (\text{By (7)}) \\
&= \text{depth}(\sigma(u')) \not\vdash \text{depth}(\sigma(u''')) \\
&> \text{depth}(\sigma(u'''')) + \text{depth}(\sigma(u''')) \\
&= \text{depth}(\sigma(u')) \not\vdash \text{depth}(\sigma(u''')) \\
&> n + 2 \\
&\quad (\text{As } \text{depth}(\sigma(u''')) > 0 \text{ and } \text{depth}(\sigma(u''')) = n + 2)
\end{align*}
\]

which is the desired contradiction.
This completes the proof for the case \( u_j = u' \not\equiv u'' \) for some terms \( u', u'' \).

The proof is now complete. \( \Box \)

We are now ready to prove Proposition 3.2 thus completing the proof of Theorem 3.2 and of our main result (Theorem 3.1).

**Proof of Proposition 3.2** Assume that \( E \) is a finite axiom system over the language \( \text{CCS} \) that is sound with respect to bisimulation equivalence, and that the following hold, for some closed terms \( p \) and \( q \) and positive integer \( n \) larger than the size of each term in the equations in \( E \):

1. \( E \vdash p \approx q \),
2. \( p \leftrightarrow q \leftrightarrow a0 \not\equiv p_n \),
3. \( p \) and \( q \) contain no occurrences of \( 0 \) as a summand or factor, and
4. \( p \) has a summand bisimilar to \( a0 \not\equiv p_n \).

We prove that \( q \) also has a summand bisimilar to \( a0 \not\equiv p_n \) by induction on the depth of the closed proof of the equation \( p \approx q \) from \( E \). Recall that, without loss of generality, we may assume that the closed terms involved in the proof of the equation \( p \approx q \) have no \( 0 \) summands or factors (by Proposition 2.1, as \( E \) may be assumed to be saturated), that applications of symmetry happen first in equational proofs (that is, \( E \) is closed with respect to symmetry), and that only closed substantial substitutions are used (\( E \) is closed with respect to \( 0 \)-substitutions).

We proceed by a case analysis on the last rule used in the proof of \( p \approx q \) from \( E \). The case of reflexivity is trivial, and that of transitivity follows immediately by using the inductive hypothesis twice. Below we only consider the other possibilities.

- **Case** \( E \vdash p \approx q \), because \( \sigma(t) = p \) and \( \sigma(u) = q \) for some equation \( (t \approx u) \in E \) and closed substantial substitution \( \sigma \). Observe, first of all, that since \( \sigma(t) = p \) and \( \sigma(u) = q \) have no \( 0 \) summands or factors, then neither do \( t \) and \( u \). Therefore, as \( n \) is larger than the size of each term mentioned in equations in \( E \), the claim follows by Proposition 5.1.

- **Case** \( E \vdash p \approx q \), because \( p = \mu p' \) and \( q = \mu q' \) for some \( p', q' \) such that \( E \vdash p' \approx q' \). This case is vacuous because \( p = \mu p' \not\equiv a0 \not\equiv p_n \), and thus \( p \) does not have a summand bisimilar to \( a0 \not\equiv p_n \).

- **Case** \( E \vdash p \approx q \), because \( p = p' + p'' \) and \( q = q' + q'' \) for some \( p', q', p'', q'' \) such that \( E \vdash p' \approx q' \) and \( E \vdash p'' \approx q'' \). Since \( p \) has a summand bisimilar to \( a0 \not\equiv p_n \), we have that so does either \( p' \) or \( p'' \). Assume, without loss of generality, that \( p' \) has a summand bisimilar to \( a0 \not\equiv p_n \).
Since \( p \) is bisimilar to \( a0 \parallel_{p_n} \), so is \( p' \). Using the soundness of \( E \) modulo bisimulation, it follows that \( q' \leftrightarrow a0 \parallel_{p_n} \). The inductive hypothesis now yields that \( q' \) has a summand bisimilar to \( a0 \parallel_{p_n} \). Hence, \( q \) has a summand bisimilar to \( a0 \parallel_{p_n} \), which was to be shown.

- **Case** \( E \vdash p \approx q \), because \( p = p' \parallel p'' \) and \( q = q' \parallel q'' \) for some \( p', q', p'', q'' \) such that \( E \vdash p' \approx q' \) and \( E \vdash p'' \approx q'' \). Since the proof involves no uses of \( 0 \) as a summand or a factor, we have that \( p', p'' \leftrightarrow 0 \) and \( q', q'' \leftrightarrow 0 \). It follows that \( q \) is a summand of itself. By our assumptions,

\[
a0 \parallel_{p_n} q' \rightarrow q.
\]

Therefore we have that \( q \) has a summand bisimilar to \( a0 \parallel_{p_n} \), and we are done.

This completes the proof. \( \square \)

### 6 Concluding Remarks

In their seminal paper [8], Bergstra and Klop showed that the parallel composition operator can be finitely axiomatized modulo bisimulation equivalence with the use of two auxiliary operators, viz. the by now classic left merge and communication merge. Independently, and at roughly the same time, Hennessy proposed the auxiliary operator \( \parallel \), and used it in [21] to give equational axiomatizations of Milner’s observation congruence [26] and timed congruence. The axiomatization of observation congruence offered by Hennessy using the \( \parallel \) operator relies, however, on a variation on the classic expansion law [26], and is therefore infinite. This led Bergstra and Klop to conjecture in [8, page 118] that Hennessy’s \( \parallel \) operator does not have a finite equational axiomatization. The main result in this paper confirms this conjecture of Bergstra and Klop’s, and answers one of the questions in [2, Problem 8], by showing that, in the presence of two distinct complementary actions, it is impossible to provide a finite axiomatization of the recursion free fragment of CCS modulo bisimulation equivalence using \( \parallel \). This result further reinforces the status of the left merge and the communication merge operators as auxiliary operators in the finite equational characterization of parallel composition in bisimulation semantics.

A natural question to ask at this point is whether there is a single *binary* operator that preserves bisimulation equivalence, and whose addition to the recursion free fragment of CCS allows for the finite equational axiomatization of parallel composition—see [2, Problem 8]. (As was recently pointed out to us by Jos Baeten and Rob van Glabbeek, it is certainly possible to obtain a finite axiomatization of bisimulation equivalence by adding one *ternary* operator to the signature of CCS.) We conjecture that no such operator exists, and that the use of two auxiliary operators is therefore necessary to achieve a finite axiomatization of parallel composition in bisimulation semantics. This result would offer the definitive justification
we seek for the canonical standing of the operators proposed by Bergstra and Klop. Work on the confirmation of this conjecture is under way, and we hope to report on it elsewhere in the near future.

Acknowledgments The work reported in this paper was carried out while Luca Aceto was on leave at Reykjavik University, and Anna Ingolfsdottir was at deCODE Genetics. They thank these institutions for their hospitality and excellent working conditions. The authors thank Zoltan Esik for pointing out useful references on the study of the equational theory of shuffle in formal language theory.
