(Received 26 February 2001; revised manuscript received 14 May 2001; published 10 December 2001)

We derive a nonsymmetrized eight-band effective-mass Hamiltonian for quantum dot heterostructures (QDH’s) in Burt’s envelope-function representation. The $8 \times 8$ radial Hamiltonian and the boundary conditions for the Schrödinger equation are obtained for spherical QDH’s. Boundary conditions for symmetrized and nonsymmetrized radial Hamiltonians are compared with each other and with connection rules that are commonly used to match the wave functions found from the bulk $k \cdot p$ Hamiltonians of two adjacent materials. Electron and hole energy spectra in three spherical QDH’s, HgS/CdS, InAs/GaAs, and GaAs/AlAs, are calculated as a function of the quantum dot radius within the approximate symmetrized and exact nonsymmetrized $8 \times 8$ models. The parameters of dissymmetry are shown to influence the energy levels and the wave functions of an electron and a hole and, consequently, the energies of both intraband and interband transitions.

I. INTRODUCTION

The $4 \times 4 k \cdot p$ hole Hamiltonian for the wave-function envelopes (so-called effective-mass Hamiltonian), that takes into account mixing of the light- and heavy-hole bands, was obtained in Ref. 1 using perturbation theory. This multiband Hamiltonian has been employed for description of the hole states in bulk crystals as well as in low-dimensional structures, in particular, in free-standing homogeneous quantum dots (QD’s). The inclusion of the mixing with the spin-orbit split-off hole band leads to the $6 \times 6 k \cdot p$ Hamiltonian which has also been applied to QD’s. To consider the nonparabolicity of the electron dispersion in narrow- and medium-gap semiconductors, it is necessary to take into account the coupling of the conduction and valence bands. Using the $k \cdot p$ perturbation theory for bulk semiconductors with cubic lattice symmetry, the $8 \times 8 k \cdot p$ model was developed in Ref. 7. This model explicitly includes eight bands around the $Γ$ point of the Brillouin zone, namely, electron, heavy-, light-, and spin-orbit split-off hole bands (each of them is twice degenerate due to the spin), and treats all other bands as remote. Along with more simple models, the $8 \times 8 k \cdot p$ Hamiltonian has been used to investigate different QD’s (see, e.g., Refs. 8–11).

Recently, experimentalists have begun to apply multiband effective-mass Hamiltonians to investigate elastic, electronic, and optical properties of multilayer nanostructures such as quantum dot heterostructures (QDH’s) CdS/HgS, InAs/GaAs, GaAs/AlAs, and CdS/HgS/CdS/H2O. However, it should be emphasized that multiband $k \cdot p$ Hamiltonians are derived for homogeneous bulk materials, i.e., under the assumption that all effective-mass parameters are constant. This is important, because at a certain step of the derivation, wave numbers $k$ are declared as operators $\hat{p}/\hbar$ that do not commute with the functions of coordinates. But, at the heterointerfaces of the multilayer nanostructures, there occurs an abrupt change of effective-mass parameters from their values in one material to those in the adjacent material. Inside a thin transitional layer that contains the heterointerface, the ordering of the differential operators and coordinate-dependent effective-mass parameters in the multiband Hamiltonian becomes crucial. In QD’s with an infinitely high confining potential for electrons and holes, all components of the wave function vanish at the heterointerface, and there remains a possibility of applying the bulk multiband $k \cdot p$ Hamiltonian straightforwardly. There are two ways to proceed from QD’s to QDH’s.

(i) The first way is to use an appropriate bulk multiband Hamiltonian for each constituent material separately, and then to match the obtained homogeneous solutions at the abrupt heterojunctions applying the connection rules (CR’s) that are usually obtained by imposing the continuity of the wave-function envelopes and of the normal to the heterointerface component of the velocity. It should be underlined that this way is heuristic and nonunique. In Ref. 18 the general CR’s, that do not even require the continuity of the wave-function envelopes, have been proposed for planar heterostructures.

(ii) The second way (cf. Refs. 19–21) is to derive a multiband Hamiltonian valid for the entire heterostructure, including the heterointerfaces, and then, if material parameters change abruptly at some interfaces, to find the boundary conditions (BC’s) for the solutions of the envelope-function equation. To find these BC’s, one should use the multiband envelope-function equation ($\hat{H} - E) \Psi = 0$ at any point of the heterostructure, including the heterointerfaces, and integrate this equation over the volume of an infinitely thin layer, which includes the considered heterointerface. Thus, the BC’s are derived starting from the requirement of continuity.
of the components of the wave function at the heterointerface.

One can always choose the CR’s physically equivalent to the BC’s. Both approaches (i) and (ii) are usually used when the wave function inside each layer of a heterostructure can be found analytically, for example in planar or spherical heterostructures. In case of an arbitrary shape of the heterointerface, approach (ii) can still be used, because, when the Hamiltonian is known for the entire heterostructure, one can find an overall numerical solution of the Schrödinger equation.

A commonly used heuristic method to obtain a multiband effective-mass Hamiltonian for heterostructures uses symmetrization of the corresponding \( k \cdot p \) Hamiltonian. This method consists of the symmetrical arrangement of the components of the momentum operator, that ensures the Hermiticity of the resulting Hamiltonian. Namely \( \beta \hat{\mathbf{p}} = [\beta(r) \mathbf{p} + \hat{\mathbf{p}} \beta(r)]/2 \) and \( \beta \hat{p} \mathbf{r} = [\hat{p} \beta(r) \mathbf{r} + \beta(r) \hat{p} \mathbf{r}]/2 \), where \( \beta(r) \) is a spatially varying effective-mass or other material-dependent parameter which is usually considered a piecewise constant, because in each layer of a heterostructure it has the value for a corresponding bulk material. The symmetrization has been applied to QDH’s in Refs. 12, 13, and 17. An essential fault of the symmetrization is that it is not a necessary condition for the multiband Hamiltonian to be Hermitian. Besides that, as will be seen below, some intrinsic properties of the heterointerface, such as reducing the symmetry of the problem and smoothing the abrupt change of the effective-mass parameters at a heterojunction, are completely neglected in the symmetrized Hamiltonian.

Burt has derived the exact envelope-function equations for a heterostructure. The order of the components of the momentum operator arises as a part of that derivation. This theory has been used by Foreman to explicitly write the effective-mass Hamiltonians for planar heterostructures. General rules for constructing the valence-band effective-mass Hamiltonians with a correct operator ordering have been described in Ref. 30 for the heterostructures with arbitrary crystallographic orientations. In Refs. 31 and 32, correct boundary conditions for planar heterostructures with wurtzite symmetry have been presented. Comparing the conduction- and valence-subband dispersion of a planar quantum well, calculated using the BC’s following from the exact nonsymmetrized and from the symmetrized effective-mass Hamiltonians, it has been shown that the former BC’s give physically reasonable results, while the latter BC’s can produce nonphysical solutions. More recently, these two sets of BC’s for a planar quantum well have been examined within the tight-binding approach. The result of the comparison allowed to give preference to the nonsymmetrized model resulting from Burt’s derivation of the envelope-function Hamiltonian, which was shown to give reliable results even when the well and barrier effective-mass parameters were very dissimilar.

In the present paper the envelope-function representation of Refs. 19–21 is used to construct the nonsymmetrized eight-band Hamiltonian for an arbitrary three-dimensional heterostructure. As an application, the electronic structure of two-layer HgS/CdS, InAs/GaAs, and GaAs/AlAs spherical QDH’s is investigated as a function of the dot radius.

It should be mentioned that the spurious solutions (“oscillating” states and “gap” states) did not become apparent in the aforementioned QDH’s. However, such solutions may appear for a different set of parameters.

The results of the calculation are compared with those obtained from the symmetrized \( 8 \times 8 \) Hamiltonian. The rest of the paper is organized as follows. In Sec. II the derivation of the nonsymmetrized eight-band Hamiltonian for a QDH is presented. The corresponding radial Hamiltonian for a spherical QDH is obtained in Sec. III. In Sec. IV the BC’s for both symmetrized and nonsymmetrized radial Hamiltonians are compared with each other and with commonly used CR’s. The results of the numerical calculation for spherical QDH’s are obtained and discussed in Sec. V. Conclusions are given in Sec. VI. The 2 \( \times \) 2 electron and 6 \( \times \) 6 hole energy-dependent nonsymmetrized Hamiltonians for a QDH, as well as radial Hamiltonians and corresponding BC’s for a spherical QDH, are found in Appendix B from the nonsymmetrized eight-band Hamiltonians.

II. NONSYMMETRIZED EIGHT-BAND HAMILTONIAN

We begin our derivation with the nonsymmetrized eight-band effective-mass Hamiltonian for a heterostructure, when the spin-orbit coupling is “turned off.” In the Bloch function basis \( |S\rangle, |X\rangle, |Y\rangle, |Z\rangle \) this Hamiltonian is represented in the following form:

\[
\hat{H}_4 = \frac{\hbar^2}{2m_0} \begin{pmatrix}
\varepsilon_z + \hbar \alpha k \\
\frac{i}{2} (v_1 \hat{k}_x + \hat{k}_y v_2) \\
\frac{i}{2} (v_1 \hat{k}_y + \hat{k}_x v_2) \\
\frac{i}{2} (v_1 \hat{k}_z + \hat{k}_y v_2)
\end{pmatrix}
\begin{pmatrix}
\varepsilon_z + \hbar \alpha k \\
\frac{i}{2} (v_1 \hat{k}_x + \hat{k}_y v_2) \\
\frac{i}{2} (v_1 \hat{k}_y + \hat{k}_x v_2) \\
\frac{i}{2} (v_1 \hat{k}_z + \hat{k}_y v_2)
\end{pmatrix}^\dagger,
\]
where $\varepsilon'_0 = \varepsilon_0 - \delta/3$, \(\hat{k} = -i \nabla\), \(\hat{k}_x,\hat{k}_y,\hat{k}_z = \hat{k} - \hat{k}_{x,y,z}\), \(\beta_1 = \gamma_1 + 4\gamma_2\), \(\beta_3 = \gamma_1 - 2\gamma_2\).

\[ v_1 = v + \xi, \quad v_2 = v - \xi, \quad \xi = \frac{v_1 + v_2}{2}, \quad \varepsilon_0 = \frac{v_1 - v_2}{2}, \quad \gamma_1 = \gamma_3 + \chi, \quad \gamma_3 = \gamma_3 - \chi. \]  

The parameters $\xi$ and $\chi$ are called the dissymmetry parameters, because when $\xi = 0$ and $\chi = 0$, the Hamiltonian (1) becomes symmetrical. The explicit form of the parameter $\xi = (v_1 - v_2)/2$ follows from the formulas (A1) and (A2) in Appendix A, and the parameter $\chi$ is determined by Eq. (7).

When the spin-orbit coupling is “turned on,” the considered eight-band Hamiltonian is represented in the Bloch function basis \([S\uparrow],X\uparrow],[Y\uparrow],Z\uparrow],[S\downarrow],X\downarrow],[Y\downarrow],Z\downarrow]\) as

\[ \hat{H}_8 = \left( \begin{array}{cc} \hat{H}_4 & 0 \\ 0 & \hat{H}_4 \end{array} \right) + \hat{H}_{so}, \]  

where $\hat{H}_4$ is defined by Eq. (1) and the spin-orbit Hamiltonian $\hat{H}_{so}$ has the form

\[ H_{so} = \frac{\Delta}{3} \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & -i & 0 & 0 & 0 & 0 & 1 \\ 0 & i & 0 & 0 & 0 & 0 & 0 & -i \\ 0 & 0 & 0 & 0 & 0 & -1 & i & 0 \\ 0 & 0 & 0 & i & 0 & 0 & 0 & 0 \\ 0 & 0 & -i & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & i & 0 & 0 & 0 & 0 & 0 \end{pmatrix}. \]  

In Eq. (1), $m_0$ is the free-electron mass, $E_c = h^2\varepsilon_c/2m_0$ is the energy of the conduction-band (CB) minimum, $E_v = h^2\varepsilon_v/2m_0$ is the energy of the valence-band (VB) maximum, $\Delta = h^2\delta/2m_0$ is the spin-orbit splitting of the VB, and $V = h\alpha/2m_0$ is the Kane velocity ($V = -ih\langle S|\hat{k}_z|Z\rangle/m_0$). Contributions of remote bands to the hole effective masses are written in terms of the “modified” Luttinger parameters

\[ \gamma_1 = \gamma_1' - E_p/3E_g, \quad \gamma_2 = \gamma_2' - E_p/6E_g, \quad \text{and} \quad \gamma_3 = \gamma_3' - E_p/6E_g, \]  

where $E_g = E_c - E_v$ is the energy gap, $E_p = 2m_0V^2$ is the Kane energy, and $\gamma_i' (i = 1, 2, 3)$ are the Luttinger parameters of the VB. Parameter $\alpha$ can be evaluated through the experimentally determined CB mass $m_c$ using the relation

\[ \frac{1}{m_c} = \frac{1}{m_0} \left( \alpha + \frac{E_p}{3} \left( \frac{2}{E_g} + \frac{1}{E_g + \Delta} \right) \right). \]  

It is worth noting that all parameters entering the Hamiltonian (4) are coordinate dependent. In a heterostructure these parameters abruptly change from the corresponding values in the adjacent material, therefore they are piecewise-constant functions of $\mathbf{r}$. Although not symmetrical, the Hamiltonian $\hat{H}_8$ is Hermitian as seen from Eq. (4). The parameters $\xi$ and $\chi$ [see Eqs. (2) and (3)] are responsible for the nonsymmetrical form of the Hamiltonian (4). The symmetrized eight-band Hamiltonian can be obtained, therefore, taking $\xi = 0$ and $\chi = 0$.

In Eq. (3), $\gamma_3$ is the contribution to $\gamma_3$ from the $\Gamma_1$ and $\Gamma_{12}$ remote bands, while $\gamma_5$ is the contribution to $\gamma_3$ from the $\Gamma_{15}$ and $\Gamma_{25}$ remote bands. Neglecting small contributions from the $\Gamma_{25}$ remote bands, the parameter $\chi(\mathbf{r})$ is determined as

\[ \chi(\mathbf{r}) = \frac{2\gamma_2(\mathbf{r}) + 3\gamma_3(\mathbf{r}) - \gamma_1(\mathbf{r}) - 1}{3}, \]  

i.e., it is explicitly defined by the effective-mass parameters of the bulk model. It is seen from Eq. (7) that in a homogeneous medium when $\gamma_i(\mathbf{r})$ are constants, $\chi(\mathbf{r})$ is also a constant, and therefore, it cancels from Eq. (1). Consequently, $\chi(\mathbf{r})$ is a specific function of a heterostructure, which gives a nonzero contribution to the Hamiltonian only at the hetero-interfaces. The value of this contribution at the point $\mathbf{r}_0$ of a heterointerface is proportional to $\chi(\mathbf{r}_0 + \mathbf{e}_n) - \chi(\mathbf{r}_0 - \mathbf{e}_n)$, where $\mathbf{e}_n$ is an infinitesimally small vector, normal to the heterointerface at the point $\mathbf{r}_0$. Parameters $v_1(\mathbf{r})$ and $v_2(\mathbf{r})$ of the Hamiltonian (1), which can be obtained from the general effective-mass equations as derived by Burt, are given in Appendix A. In the definition (2), the functions $v_1(\mathbf{r})$ and $v_2(\mathbf{r})$ are subdivided into the symmetric $v(\mathbf{r})$ and antisymmetric $\xi(\mathbf{r})$ parts, where $\xi(\mathbf{r})$, like $\chi(\mathbf{r})$ above, is a specific parameter of a heterostructure. In general, $\xi(\mathbf{r})$ is a piecewise-constant function of $\mathbf{r}$. The necessary and sufficient condition for $\xi(\mathbf{r})$ to give a nonzero contribution to the $8 \times 8$ Hamiltonian only at the heterointerfaces, and to become a constant in the homogeneous medium, simultaneously with $v(\mathbf{r})$, is

\[ \xi(\mathbf{r}) = c_{\xi} v(\mathbf{r}), \]  

where the coefficient of proportionality $c_{\xi}$ is constant over the entire heterostructure. Equation (8) is the general form of $\xi(\mathbf{r})$ only for a two-layer heterostructure. For an $N$-layer heterostructure, there can be $N - 1$ independent constants — one for each heterointerface. Each constant for a given heterointerface can be found experimentally considering a two-layer heterostructure (see Sec. V).

In order to diagonalize the spin-orbit Hamiltonian $H_{so}$, it is convenient to carry out a unitary transformation of the Bloch function basis \([S\uparrow],[X\uparrow],[Y\uparrow],[Z\uparrow],[S\downarrow],[X\downarrow],[Y\downarrow],[Z\downarrow]\) into the following Bloch function basis:

\[ u_{1/2,1/2}^{s_1} = [S\uparrow], \]  

\[ u_{1/2,-1/2}^{s_1} = [S\downarrow], \]  

\[ u_{3/2,3/2}^{s_1} = \frac{1}{\sqrt{2}}([X\uparrow] + i[Y\uparrow]), \]  

\[ u_{3/2,-3/2}^{s_1} = i \sqrt{2} ([X\downarrow] + i[Y\downarrow] - 2[Z\downarrow]), \]  

\[ u_{5/2,5/2}^{s_1} = \frac{1}{\sqrt{6}}([X\uparrow] - i[Y\uparrow] + 2[Z\downarrow]), \]  

\[ u_{5/2,-5/2}^{s_1} = \frac{1}{\sqrt{6}}([X\downarrow] - i[Y\downarrow] + 2[Z\downarrow]). \]
momentum, and $\mu = J_z$ is its $z$ component. The eight-band Hamiltonian $\hat{H}$ in the new basis can be obtained now after a unitary transformation

$$\hat{H} = U^* \hat{H}_0 U^T,$$

where $U$ is the matrix of the transformation from the basis $\{|S\uparrow\rangle, |X\uparrow\rangle, |Y\uparrow\rangle, |Z\uparrow\rangle, |S\downarrow\rangle, |X\downarrow\rangle, |Y\downarrow\rangle, |Z\downarrow\rangle\}$ to the new basis $\{u^v_{1/2,1/2}, u^v_{1/2,-1/2}, u^v_{3/2,1/2}, u^v_{3/2,-1/2}, u^v_{5/2,3/2}, u^v_{5/2,-3/2}, u^v_{1/2,1/2}, u^v_{1/2,-1/2}\}$. $U$ is defined by Eqs. (9) and (10). Performing the transformation (11), one obtains

$$\mathbf{H} = \frac{\hbar^2}{2m_0} \begin{pmatrix}
\varepsilon_c + T & 0 & iV_1 & \sqrt{\frac{2}{3}}V_0 & \frac{i}{\sqrt{3}} V_{-1} & 0 & \frac{i}{\sqrt{3}} V_0 & \sqrt{\frac{2}{3}} V_{-1} \\
0 & \varepsilon_c + T & 0 & -\frac{1}{\sqrt{3}} V_1 & i \sqrt{\frac{2}{3}} V_0 & -V_{-1} & i \sqrt{\frac{2}{3}} V_1 & -\frac{1}{\sqrt{3}} V_0 \\
-iV_1^\dagger & 0 & \varepsilon_v - P - Q & -S & -R & 0 & -\frac{i}{\sqrt{2}} S & i \sqrt{2} R \\
\sqrt{\frac{2}{3}} V_0 & -\frac{1}{\sqrt{3}} V_1^\dagger & -i \sqrt{\frac{3}{2}} S^\dagger & \varepsilon_v - P + Q & -C & -R & i \sqrt{2} Q & -i \sqrt{\frac{3}{2}} \Sigma \\
-iV_{-1}^\dagger & 0 & -R^\dagger & S^\dagger & \varepsilon_v - P^* + Q^* & i \sqrt{2} R^\dagger & i \sqrt{2} S^\dagger & C \\
0 & 0 & -R^\dagger & S & \varepsilon_v - P^* - Q^* & i \sqrt{2} R^\dagger & i \sqrt{2} S & \varepsilon_v^* - P \\
-iV_0^\dagger & 0 & -i \sqrt{\frac{3}{2}} S^\dagger & -i \sqrt{2} Q & -i \sqrt{\frac{3}{2}} \Sigma^\dagger & -i \sqrt{2} R & i \sqrt{\frac{3}{2}} S^\dagger & C^\dagger & \varepsilon_v^* - P^* \end{pmatrix}.$$  

(12)

where $\varepsilon_v'' = \varepsilon_v - \delta$,

$$\begin{align*}
\hat{k}_+ &= \frac{\hat{k}_+ + i \hat{k}_-}{\sqrt{2}}, \\
\hat{k}_- &= \frac{\hat{k}_+ - i \hat{k}_-}{\sqrt{2}}, \\
V_1 &= \frac{1}{2}(v_1 \hat{k}_+ + \hat{k}_+ v_2), \\
V_{-1} &= \frac{1}{2}(v_1 \hat{k}_- + \hat{k}_- v_2).
\end{align*}$$

In Eq. (12), daggers ($^\dagger$) denote the Hermitian conjugation, i.e., $A^\dagger = (A^T)^*$ [it is important to note that $(v_1 \hat{k}_+)^\dagger = \hat{k}_+ v_{1,2}$ and $(v_1 \hat{k}_-)^\dagger = \hat{k}_- v_{1,2}$]. Unlike the bulk $8 \times 8 \mathbf{k} \cdot \mathbf{p}$ Hamiltonian where the matrix element $C$ is zero, in the Hamiltonian (12) the Bloch functions $u^v_{5/2,1/2}$ and $u^v_{3/2,-1/2}$ are

$$\begin{align*}
R &= \sqrt{3}(\hat{k}_+ (\gamma_2 - \gamma_3) \hat{k}_+ + \hat{k}_- (\gamma_2 + \gamma_3) \hat{k}_-), \\
S &= -i \sqrt{6}(\hat{k}_- (\gamma_3 + \chi) \hat{k}_+ + \hat{k}_- (\gamma_3 - \chi) \hat{k}_-), \\
\Sigma &= -i \sqrt{6}(\hat{k}_- (\gamma_3 - \chi) \hat{k}_+ + \hat{k}_- (\gamma_3 + \chi) \hat{k}_-), \\
C &= -i 2 \sqrt{2} (\hat{k}_-  \hat{k}_+). \end{align*}$$  

(13)
coupled with each other, as well as the functions \( u_{1/2,1/2}^c \) and \( u_{1/2,-1/2} \). As seen from Eq. (13), this coupling arises because of the dissymmetry parameter \( \chi \), which can reduce, in this way, the symmetry of the problem. The Hamiltonian so obtained can be used to investigate electronic properties of quantum-well, quantum-wire, and quantum dot heterostructures.

### III. EIGHT-BAND HAMILTONIAN FOR A SPHERICAL QDH

To study the electronic structure of spherical QDH’s, the spherical approximation \(^2\) (i.e., \( \gamma^L = \gamma^j = \gamma^c \)) can be applied. If we take \( \gamma^L = (2 \gamma^j + 3 \gamma^L)/5 \), then the quantum states so obtained are correct to the first order of the perturbation theory. Using the relations between the Luttinger parameters \( \gamma^L_j \) and the “modified” Luttinger parameters \( \gamma_j \) we have

\[
\gamma = (2 \gamma^c + 3 \gamma^s)/5, \quad (14)
\]

and according to Eq. (7)

\[
\chi = (5 \gamma - \gamma_1 - 1)/3. \quad (15)
\]

In spherical QDH’s, where all effective-mass parameters depend only on the absolute value \( r \) of the radius vector, electron and hole states are eigenfunctions of the total angular momentum \( j \) and its \( z \) component \( m = j_z \). Therefore, the electron or hole wave function can be written as a linear expansion in the eight Bloch functions \( u_{j,\mu} \):

\[
\Psi_{j,m}(r) = \sum_{j,\mu} F_{j,\mu}^{(c),m}(r) u_{j,\mu} + \sum_{j,\mu} F_{j,\mu}^{(v),m}(r) u_{j,\mu}^c. \quad (16)
\]

where the envelope functions \( F_{j,\mu}^{(c),m}(r) \) are defined in the chosen Bloch function bases (9) and (10) as

\[
F_{1/2,\mu}^{(c),m}(r) = \sum_{l,\lambda} C_{1/2,\mu,j,l}^{i,m} R_{1/2,\mu}^{c,j}(r) Y_{l,\lambda}(\theta, \phi),
\]

\[
F_{3/2,\mu}^{(c),m}(r) = i^{\mu-3/2} \sum_{l,\lambda} C_{3/2,\mu,1,j}^{i,m} R_{3/2,\mu}^{c,j}(r) Y_{l,\lambda}(\theta, \phi),
\]

\[
F_{1/2,\mu}^{(v),m}(r) = i^{1/2-\mu} \sum_{l,\lambda} C_{1/2,\mu,1,j}^{i,m} R_{1/2,\mu}^{v,j}(r) Y_{l,\lambda}(\theta, \phi). \quad (17)
\]

Here, \( R_{j,\mu}^{c,j}(r) \) are the radial envelope functions, \( C_{j,\mu,j,l}^{i,m} \) are the Clebsch-Gordan coefficients, and \( Y_{l,\lambda}(\theta, \phi) \) are the spherical harmonics. Noting that in the matrix representation of the Hamiltonian (12) \( u_{1/2,1/2} = (1 0 0 0 0 0 0 0)^T \), \( u_{1/2,-1/2} = (0 0 0 0 0 0 0 1)^T \) one can rearrange Eq. (16) into the form

\[
\Psi_{j,m}(r) = \sum_{l,\lambda} R_{l,\mu}^{c,j}(r) Y_{l,\lambda}(\theta, \phi) + \sum_{l,\lambda} R_{3/2,\mu}^{v,j}(r) Y_{l,\lambda}(\theta, \phi) + \sum_{l,\lambda} R_{1/2,\mu}^{v,j}(r) Y_{l,\lambda}(\theta, \phi) + \sum_{l,\lambda} R_{1/2,\mu}^{v,j}(r) Y_{l,\lambda}(\theta, \phi), \quad (18)
\]

where the \( 8 \times 8 \) matrix \( R_{j,\mu}^{c,j}(r) \) next to the eight radial envelope functions \( R_{j,\mu}^{v,j}(r) \), for a given \( j \), can be found by comparing Eq. (18) with Eqs. (16) and (17). Now, integrating over the angular variables \( \theta \) and \( \phi \), it is possible to obtain the radial Hamiltonian

\[
\hat{H}_j = \int \left( \gamma^{b,j,m}_r(\theta, \phi) \right) \hat{H} \gamma^{b,j,m}_r(\theta, \phi) d\Omega, \quad (19)
\]

corresponding to the radial Schrödinger equation

\[
\sum_{b,j} \hat{H}_j \gamma^{b,j,m}_r(\theta, \phi) = E \gamma^{b,j,m}_r(\theta, \phi), \quad (20)
\]

where \( E \) is the electron or hole eigenenergy to be determined, and \( b = c \) or \( v \). The Hamiltonian (19) does not depend on \( m \), because within the spherical approximation the energy spectrum is degenerate with respect to the \( z \) component of the total momentum.

After some algebra, we derive the following relations for the spherical harmonics:

\[
\hat{k}_+ Y_{l,\lambda}(\theta, \phi) = C_{l+1,\lambda+1;1,0}^{i,0} B_{l+1,\lambda+1} Y_{l+1,\lambda+1}(\theta, \phi),
\]

\[
\hat{k}_- Y_{l,\lambda}(\theta, \phi) = -C_{l-1,\lambda-1;1,0}^{i,0} B_{l-1,\lambda-1} Y_{l-1,\lambda-1}(\theta, \phi),
\]

\[
\hat{k}_z Y_{l,\lambda}(\theta, \phi) = C_{l,\lambda;1,1}^{i,0} B_{l+1,\lambda} Y_{l+1,\lambda}(\theta, \phi),
\]

\[
+ C_{l-1,\lambda-1;1,1}^{i,0} B_{l-1,\lambda-1} Y_{l-1,\lambda-1}(\theta, \phi), \quad (21)
\]

where

\[
B_{l+1}^+ = -i \sqrt{l+1 \over 2l+1} A_{l+1}^{(1)}, \quad B_{l-1}^- = i \sqrt{l \over 2l-1} A_{l-1}^{(-1)},
\]

\[
A_{l}^{(p)} = -\frac{\partial}{\partial r} + \frac{l+1/2-p/2}{r}. \quad (22)
\]

Using the relations (21), the radial Hamiltonian (19) can be obtained in an explicit form. If we choose the following order of the radial functions \( R_{1/2,1/2}^{\pm}, R_{3/2,1/2}^{\pm}, R_{5/2,1/2}^{\pm}, R_{3/2,-1/2}^{\pm}, R_{5/2,-1/2}^{\pm}, R_{3/2,1/2}^{\pm}, R_{5/2,1/2}^{\pm}, R_{3/2,-1/2}^{\pm}, R_{5/2,-1/2}^{\pm}, \) then the \( 8 \times 8 \) matrix of the Hamiltonian \( \hat{H}_j \) takes the form

\[
\hat{H}_j = \begin{pmatrix}
\hat{H}^{(1)}_j & 0 \\
0 & \hat{H}^{(-1)}_j
\end{pmatrix}. \quad (23)
\]

Here, \( \hat{H}^{(1)}_j \) is the \( 4 \times 4 \) Hamiltonian of the “even” states and
\( \mathcal{K}_j^{(-1)} \) is the \( 4 \times 4 \) Hamiltonian of the “odd” states. It is seen that the parity \( p \) (\( p = 1 \) for even states and \( p = -1 \) for odd states) is conserved in the spherical approximation, even

\[
\mathcal{H}_j^{(p)} = \frac{\hbar^2}{2m_0} \begin{pmatrix}
\epsilon - T_{j-p/2} & a_{j}^{(p)} A_{j+1/2}^{(p)} \\
a_{j}^{(p)} B_{j-p/2}^{(p)} & e_{v} + T_{j+1/2} - c_{j}^{p} Q_{j-p/2}^{(p)} \\
b_{j}^{(p)} B_{j-p/2}^{(p)} & p \sqrt{2} A_{j-p/2}^{(p)} \\
p \sqrt{2} B_{j-p/2}^{(p)} & p \sqrt{2} \Delta_{j-p/2}^{(p)}
\end{pmatrix},
\]

where \( a_{j}^{p} = \sqrt{1+3 \eta_j^p} \), \( b_{j}^{p} = \sqrt{3(1-\eta_j^p)} \), \( c_{j}^{p} = 1-3 \eta_j^p \), \( \eta_j^p = p/(2j+1-p) \).

\[
A_{j}^{(p)} = \frac{1}{2 \sqrt{6}} \left( v_{1} A_{j}^{(p)} + A_{j}^{(p)} v_{2} \right),
\]

\[
B_{j}^{(p)} = \frac{1}{2 \sqrt{6}} \left( v_{2} A_{j}^{(p)} + A_{j}^{(p)} v_{1} \right),
\]

\[
\mathcal{R}_{j}^{(p)} = -A_{j+1/2}^{(p)} \gamma A_{j}^{(p)}.
\]

Introducing the operator

\[
\Delta^{(p)}(\beta) = -A_{j+1/2}^{(p)} \beta A_{j}^{(p)},
\]

we can represent \( T_{j}^{(p)} \), \( \mathcal{P}_{j}^{(p)} \), and \( Q_{j}^{(p)} \) as

\[
T_{j}^{(p)} = \frac{(l+1) \Delta^{(1)}(\alpha) + l \Delta^{(-1)}(\alpha)}{2l+1},
\]

\[
\mathcal{P}_{j}^{(p)} = \frac{(l+1) \Delta^{(1)}(\gamma) + l \Delta^{(-1)}(\gamma)}{2l+1} + \Delta^{(p)}(\gamma),
\]

\[
Q_{j}^{(p)} = \frac{(l+1/2) \Delta^{(1)}(\gamma-\chi) + (l+3/2) \Delta^{(-1)}(\gamma-\chi)}{2l+1} + \Delta^{(p)}(\chi).
\]

Inside each spherical layer, the radial Hamiltonian (24) for a spherical QDH coincides with the bulk radial Hamiltonian from Ref. 9 for a spherical QD, when the following notations for the radial functions are used:

\[
R_{1/2,j-1/2}^{(a)} = R_{-}^{(a)}, \quad R_{1/2,j+1/2}^{(a)} = -R_{-}^{(a)},
\]

\[
R_{3/2,j+1}^{(a)} = R_{+}^{(a)}, \quad R_{3/2,j-1}^{(a)} = R_{-}^{(a)},
\]

\[
R_{5/2,j+3/2}^{(a)} = -R_{+}^{(a)}, \quad R_{5/2,j+1/2}^{(a)} = -R_{-}^{(a)},
\]

\[
R_{5/2,j-1}^{(a)} = R_{+}^{(a)}, \quad R_{5/2,j-3/2}^{(a)} = R_{-}^{(a)}.
\]

Therefore, in order to find the radial wave functions \( R_{j}^{(a)} \) inside each spherical layer, one can use the same technique as in Ref. 9. When the wave functions inside each spherical layer are known, the BC’s should be applied to match the wave functions from two adjacent layers.

**IV. BOUNDARY CONDITIONS FOR A SPHERICAL QDH**

When considering the multiband models for planar heterostructures, the BC’s for the wave function are often obtained by integrating the Schrödinger equation across the heterointerface and assuming the continuity of the wavefunction envelopes. The resulting BC’s are of the following form:

\[
\Psi_{A}|_{z=-0} = \Psi_{B}|_{z=-0}, \quad \tilde{J}_{z} \Psi_{A}|_{z=-0} = \tilde{J}_{z} \Psi_{B}|_{z=-0},
\]

where \( A \) and \( B \) are two materials separated by the heterointerface \( z=0 \), and \( \tilde{J}_{z} \) is the normal to the heterointerface component of the current operator. The aforementioned integration is actually justified only for Burt’s envelope-function equations, because only these have been shown to be valid at the heterointerface. Analogously to the case of planar heterostructures, for spherical QDH’s one integrates the radial Schrödinger equation

\[
(\mathcal{H}_{j}^{(p)} - E_{j}^{(p)}) R_{j}^{(p)} = 0, \quad R_{j}^{(p)} = \begin{pmatrix}
R_{1/2,j-1/2}^{(a)} \\
R_{3/2,j+1}^{(a)} \\
R_{5/2,j+3/2}^{(a)} \\
R_{5/2,j-1}^{(a)}
\end{pmatrix},
\]

where \( \mathcal{H}_{j}^{(p)} \) is defined by Eq. (24) and \( E_{j}^{(p)} \) is the eigenvalue. This integration is carried out across the point \( r=a \), where \( r=a \) is the spherical heterointerface that separates two materials: \( A \) (at \( r<a \)) and \( B \) (at \( r>a \)). Including the continuity of the radial wave function \( R_{j}^{(p)} \), the required BC’s have the form

\[
(\mathcal{H}_{j}^{(p)})_{A}|_{r=a-0} = (\mathcal{H}_{j}^{(p)})_{B}|_{r=a+0}, \quad \tilde{J}_{j}^{(p)} R_{j}^{(p)}|_{r=a-0} = \tilde{J}_{j}^{(p)} (R_{j}^{(p)})_{B}|_{r=a-0}.
\]

Here the radial component of the current operator \( \tilde{J}_{j}^{(p)} \) is
obtained from the radial Hamiltonian $\hat{\mathcal{H}}_{j}^{(p)}$ using the following procedure. In those terms of the Hamiltonian (24) that contain the operator $A_{j}^{(p)}$, the utmost left-hand side $A_{j}^{(p)}$ is replaced by $-p$ [in conformity with Eq. (22)]; the rest of the terms are set to zero, and the result is multiplied by $2i\hbar$. Thus we find

$$
\hat{\mathcal{J}}_{j}^{(p)} = \frac{i\hbar}{m_{0}} \begin{pmatrix}
-\alpha \frac{\partial}{\partial r} & \frac{p}{2\sqrt{6}} a_{j}^{(p)}(v-\xi) \\
-\frac{p}{2\sqrt{6}} b_{j}^{(p)}(v+\xi) & \gamma_{1} \frac{\partial}{\partial r} - c_{j}^{(p)} \gamma D_{r} + f_{j}^{(p)} \frac{X}{r} \\
-\frac{p}{2\sqrt{6}} b_{j}^{(p)}(v+\xi) & -p a_{j}^{(p)} b_{j}^{(p)} \gamma A_{j}^{(-p)} + \frac{1}{2\sqrt{3}}(v-\xi) \\
\end{pmatrix},
$$

(32)

where

$$
D_{r} = \frac{\partial}{\partial r} + \frac{3/2}{r}, \quad f_{j}^{(p)} = p(j + 1/2 - np/2). \quad (33)
$$

While the radial Hamiltonian $\hat{\mathcal{H}}_{j}^{(p)}$ is Hermitian, the radial component of the current operator $\hat{\mathcal{J}}_{j}^{(p)}$ is not [as seen from Eq. (32)].

It is important to compare the obtained BC's (31) and (32) with the commonly used CR's (the wave function and the normal component of the velocity are continuous at the heterointerface).\(^\text{11,16}\) The velocity operator $\hat{\mathcal{V}}$ is defined as

$$
\hat{\mathcal{V}} = \frac{i}{\hbar}[\hat{\mathcal{H}}, \hat{r}] = \frac{\hbar}{\partial} \frac{\partial \hat{H}}{\partial \hat{k}}, \quad (34)
$$

where the Hamiltonian $\hat{\mathcal{H}}$ has been determined earlier by Eq. (12). Therefore, the normal component of the velocity operator is obtained as follows:

$$
\hat{\mathcal{V}}_{r} = \frac{1}{\hbar} \frac{r}{\hbar} \frac{\partial \hat{H}}{\partial \hat{k}} = \frac{1}{\hbar} \left( n_{+} \frac{\partial \hat{H}}{\partial \hat{k}_{+}} + n_{-} \frac{\partial \hat{H}}{\partial \hat{k}_{-}} + n_{z} \frac{\partial \hat{H}}{\partial \hat{k}_{z}} \right), \quad (35)
$$

where

$$
n_{+} = \frac{x + iy}{r\sqrt{2}}, \quad n_{-} = \frac{x - iy}{r\sqrt{2}}, \quad n_{z} = \frac{z}{r}. \quad (36)
$$

The differentiation of the Hamiltonian can be realized in such a way that

$$
\hat{\mathcal{V}}_{r} = \hat{\mathcal{V}}_{r}^{p} + \hat{\mathcal{V}}_{r}^{L}, \quad (37)
$$

where

$$
\hat{\mathcal{V}}_{r}^{L} = \frac{1}{\hbar} \left( n_{+} \frac{\partial \hat{H}^{L}}{\partial \hat{k}_{+}} + n_{-} \frac{\partial \hat{H}^{L}}{\partial \hat{k}_{-}} + n_{z} \frac{\partial \hat{H}^{L}}{\partial \hat{k}_{z}} \right), \quad (38)
$$

Here $\hat{\mathcal{H}}^{L}$ ($\hat{\mathcal{H}}^{R}$) denotes the Hamiltonian, in which the right(left)-hand operators $\hat{k}_{+}$, $\hat{k}_{-}$, and $\hat{k}_{z}$ are treated as $c$ numbers, i.e., only the left(right)-hand operators $\hat{k}_{+}$, $\hat{k}_{-}$, and $\hat{k}_{z}$ are differentiated. Using the explicit form of the Hamiltonian $\hat{\mathcal{H}}$ [see Eq. (12)], one finds that $\hat{\mathcal{V}}_{r}$ can be obtained multiplying by $1/\hbar$ the Hamiltonian $\hat{\mathcal{H}}$, in which all the left-hand operators $\hat{k}_{+}$, $\hat{k}_{-}$, and $\hat{k}_{z}$ are replaced by $n_{+}$, $n_{-}$, and $n_{z}$, correspondingly, while all the terms that do not contain the former operators are set to zero. It can be also shown that

$$
\hat{\mathcal{V}}_{r}^{p}(\xi, \chi) = \hat{\tau} \hat{\mathcal{V}}_{r}^{p}(-\xi, -\chi), \quad (39)
$$

where the operator $\hat{\tau}$ draws all effective-mass parameters through the operators $\hat{k}_{+}$, $\hat{k}_{-}$, and $\hat{k}_{z}$ to the utmost right-hand positions.

The radial velocity $\hat{\mathcal{V}}_{r}^{(p), L}$ is obtained from $\hat{\mathcal{V}}_{r}^{L}$ in the same way that the radial Hamiltonian $\hat{\mathcal{H}}_{j}^{(p)}$ was obtained from $\hat{\mathcal{H}}$, i.e., by the definition (19). For $n_{+}$, $n_{-}$, and $n_{z}$ [see Eq. (36)] the expressions similar to Eq. (21) are valid if one replaces $-iA_{j}^{(p)}$ by $-p$. Therefore, $\hat{\mathcal{V}}_{r}^{(p), L}$ can be found by multiplying the Hamiltonian $\hat{\mathcal{H}}_{j}^{(p)}$ by $i/\hbar$, replacing all the left-hand operators $A_{j}^{(p)}$ by $-p$, and setting all the terms, which do not contain the operator $A_{j}^{(p)}$, to zero. This procedure results in

$$
\hat{\mathcal{V}}_{r}^{(p), L} = \frac{1}{2} \hat{\mathcal{J}}_{j}^{(p)}, \quad (40)
$$

where $\hat{\mathcal{J}}_{j}^{(p)}$ has been defined by Eq. (32). Using Eqs. (37), (40), and (39) one obtains
\[
\hat{V}_j^{(p)} = \frac{1}{2} \left[ \hat{J}_j^{(p)}(\xi, \chi) + \hat{J}_j^{(p)}(-\xi, -\chi) \right].
\] (41)

Considering the explicit form of the matrix \(\hat{J}_j^{(p)}\) we see that all the terms, containing parameters \(\xi\) and \(\chi\), responsible for the nonsymmetrical form of the Hamiltonian, cancel. Consequently, we obtain

\[
\hat{V}_j^{(p)} = \frac{1 + \tau}{2} \hat{J}_j^{(p)}(\xi = 0, \chi = 0).
\] (42)

If all the effective-mass parameters are piecewise-constant functions of \(\tau\), then at any point of the heterostructure except the spherical heterointerfaces, we can replace \(\hat{\tau}\) by 1, and therefore

\[
\hat{V}_j^{(p)} = \hat{J}_j^{(p)}(\xi = 0, \chi = 0).
\] (43)

It is clearly seen now that the commonly used CR’s for spherical QDH’s (Refs. 11 and 16) are the same as BC’s (31) and (32) obtained from the symmetrized Hamiltonian \((\xi = 0, \chi = 0)\). Like \(\hat{J}_j^{(p)}\), the radial component of the velocity operator (42) is not Hermitian when \(\tau = 1\). Therefore, in order to prove that both current and velocity are conserved simultaneously, we should verify whether the real parts of the current density and of the velocity density are the same, i.e., we should check whether the equality

\[
\text{Re}[\langle R_j^{(p)} | \hat{J}_j^{(p)} | R_j^{(p)} \rangle] = \text{Re}[\langle \hat{J}_j^{(p)} | \hat{V}_j^{(p)} | \hat{J}_j^{(p)} \rangle] \tag{44}
\]

holds true. Here \(R_j^{(p)}\) is the radial wave function defined by Eq. (30). Substituting Eq. (32) into the left-hand side of Eq. (44), we see that all the terms containing the parameters \(\xi\) and \(\chi\) cancel, because their contribution to the current density is purely imaginary. Therefore, in conformity with Eq. (43), Eq. (44) is proven to be fair.

V. RESULTS OF THE CALCULATION AND DISCUSSION

In this section we investigate the electronic structure of three spherical QDH’s with different values of the energy gaps: a zero-gap semiconductor embedded into a wide-gap semiconductor (HgS/CdS), a narrow-gap semiconductor embedded into a medium-gap semiconductor (InAs/GaAs), and a medium-gap semiconductor embedded into a wide-gap semiconductor (GaAs/AlAs). Note that in these widely used experimentally relevant materials, the effective-mass parameters are substantially different. The bulk eight-band parameters of the used III-V and IV-VI materials are listed in Tables I and II, correspondingly. For electron and hole levels, obtained within the spherical eight-band model, we use a common notation: \(nQ_j^{(e)}\) denotes an electron state and \(nQ_j^{(h)}\) denotes a hole state, where \(n\) is the number of the level with a given symmetry and \(Q = S, P, D, \ldots\) denotes the lowest value of the momentum \(l\) in the spherical harmonics of Eq. (18) in front of the CB Bloch functions for an electron state and in front of the VB Bloch functions for a hole state, i.e., \(Q = j - p/2\) for an electron and \(Q = \min(j + p/2, j - 3p/2)\) for a hole.

A. Electron energy levels

The electron energy levels of the HgS/CdS, InAs/GaAs, and GaAs/AlAs QDH’s are depicted in Figs. 1–3, corre-

FIG. 1. All the discrete electron energy levels in the HgS/CdS QDH as a function of the quantum dot radius. The $P_{3/2}^{(e)}$ and $D_{5/2}^{(e)}$ energy levels are not shown here nor in Figs. 2 and 3 because in the chosen scale they coincide with the levels $P_{5/2}^{(e)}$ and $D_{5/2}^{(e)}$, correspondingly. Solid lines represent the result of the symmetrized eight-band model ($c_\xi = 0, \chi = 0$). With the nonsymmetrized valence-band part of the Hamiltonian ($\chi \neq 0$), dashed lines show the case $c_\xi = 0$ while grey bands represent the continuous change of $c_\xi$ from 1 to $-1$. The grey bands refer to a possible variation in energy due to conduction-band/valence-band coupling via the position dependence of the interband momentum matrix element. Here and in Figs. 2–6, the inset with inscriptions correspondingly, as a function of the quantum dot radius. Other denotations are chosen scale they coincide with the levels $P_{1/2}^{(e)}$ and $D_{5/2}^{(e)}$.

Analyzing Figs. 1–3 we arrive at the following empirical formula, which determines the energy shift of all electron energy levels on $n = 1$ when a nonzero value of the parameter $\chi$ is considered:

$$E_e - E_e|_{\chi=0} = - \frac{\hbar^2}{m_0 a^2} (\chi_1 - \chi_2).$$

(45)

Here the indices “1” and “2” denote interior and exterior materials, correspondingly. For $n > 1$ the value of this shift is much smaller than for $n = 1$. It is seen that the shift $E_e$ decreases with increasing $a$ and with increasing the energy gap in the interior material. Such a behavior of the parameter $b$ is connected with the fact that it is proportional to the value of hole radial components of the electron wave function at the heterointerface. It is clear now that the observed strong dependence of the energy levels in the HgS/CdS QDH on $c_\xi$ (see Fig. 1) is due to the large value of the difference $\sqrt{E_{p1/2}^{(e)}} - \sqrt{E_{p5/2}^{(e)}}$ and to the zero energy gap in HgS. For two other QDH’s the dependence of the energy levels on $c_\xi$ is a few times weaker than that for the HgS/CdS QDH.

Hence, Eqs. (45) and (46) allow us to estimate corrections to the eigenenergies due to the replacement of the heuristic symmetrized Hamiltonian with the nonsymmetrized Hamiltonian avoiding complicated calculations. It follows from Eq. (45) that such corrections rise with a decreasing quantum dot radius.
TABLE III. The spin-orbital splitting of electron energy levels (at \( c_\xi = -1 \)), the energy-dependent electron effective masses (at \( c_\xi = -1 \)), the energy shift of electron and hole levels due to finite values of \( \chi \) (at \( c_\xi = 0 \)), and the difference of \( \chi \) in adjacent materials for the 6×6 model (at \( c_\xi = 1 \)). If not indicated explicitly, \( \chi \neq 0 \). \( E_e \) and \( E_h \) are the electron and hole ground-state energies corresponding to the states \( 1S_{1/2}^{(e)} \) and \( 1S_{3/2}^{(h)} \). The indices “1” and “2” denote the interior and exterior materials, correspondingly.

\(^a\)The theoretical estimate based on the 2×2 energy-dependent Hamiltonian for an electron (see Appendix B) is given in parentheses.

\(^b\)The corresponding bulk effective mass (see Tables I and II) is given in parentheses.

\(^c\)The result of the empirical estimate \( E_{(e,h)}|_x=0 = -(h^2/2m_0 \sigma^2)(\chi_1 - \chi_2) \) is given in parentheses.

\(^d\)The difference \( \chi_1 - \chi_2 \) for the eight-band model (see Tables I and II) is given in parentheses.

radius as \( 1/a^2 \). Therefore, one should use the nonsymmetrized Hamiltonian for a description of quantum dots with small radii.

B. Hole energy levels

All the hole energy levels of \( S \) and \( P \) types in the HgS/CdS QDH, with \( j = 3/2 \) in the InAs/GaAs QDH’s and with \( j = 3/2 \) in the GaAs/AlAs QDH’s are depicted in Figs. 4–6, correspondingly, as a function of the quantum dot radius. It is seen from these figures that the empirical formula (45) holds for hole levels, too, i.e., for a nonzero value of \( \chi \), the hole energy levels shift in the same direction as the electron energy levels do. For the HgS/CdS QDH (\( a = 2 \) nm) the shift of the hole ground-state level is about 9 meV, which is smaller than the shift of the electron ground-state level. At the same time, for InAs/GaAs (\( a = 4 \) nm) and GaAs/AlAs (\( a = 3 \) nm) QDH’s the shift for the hole ground-state level is almost the same as that for the electron ground-state level (see Table III). For the higher hole levels (\( n > 1 \)) the value of the shift under consideration decreases with increasing \( n \), much weaker than it does for the electron levels.

The dependence of the hole levels on the parameter \( c_\xi \) is substantially different from such a dependence for the electron levels. The formula (46) can be approximately applied here only for the level \( 1S_{3/2}^{(h)} \), which is the hole ground-state energy for all examined QDH’s. It is seen that this energy level strongly depends on \( c_\xi \) even for InAs/GaAs and GaAs/AlAs QDH’s. All the other hole energy levels under analysis depend on \( c_\xi \) very weakly, and such a dependence is revealed only in Fig. 4 for the HgS/CdS QDH.

C. Electron and hole wave functions and pair energies

In Figs. 7–9, the \( S \) components of the radial wave functions of the electron ground state (\( 1S_{1/2}^{(e)} \)) and of the hole ground state (\( 1S_{3/2}^{(h)} \)) are depicted for HgS/CdS (\( a = 2 \) nm), InAs/GaAs (\( a = 4 \) nm), and GaAs/AlAs (\( a = 3 \) nm) QDH’s, correspondingly. It is seen that in all these QDH’s, the hole density in the interior material is higher than the electron density, and the electron density is higher in the exterior material. It is also seen that when \( c_\xi \) changes from 1 to \(-1 \), the electron density in the centers of the HgS/CdS and InAs/GaAs QDH’s increases and the hole density decreases. The opposite trends of behavior of the electron and hole densities are observed in the center of the GaAs/AlAs QDH. The abrupt change of the derivative of the electron radial component with the change of \( c_\xi \) is well seen at the heterointerfaces of all QDH’s under consideration. At the same time, the derivative of the hole radial component changes smoothly. The contribution of the hole radial components to the density of the electron state (at \( c_\xi = 0 \)) is as high as 33% for HgS/CdS, 20% for InAs/GaAs, and 14% for GaAs/AlAs QDH’s. Such contributions show that the nonparabolicity of the electron dispersion law is substantial even for the QDH’s of the medium-gap semiconductors (GaAs) and certainly should be taken into consideration when the QDH’s of the narrow-gap semiconductors (InAs) are investigated. The contribution of the electron radial component to the density of the hole state (at \( c_\xi = 0 \)) is 6% for HgS/CdS, 1% for InAs/GaAs, and 1% for GaAs/AlAs QDH’s. This fact leads to the conclusion that the additional nonparabolicity of the hole dispersion law connected with the influence of the conduction band can be neglected for both narrow- and medium-gap semiconductor QD’s.

Taking into account the principal role of the dissymmetry coefficient \( c_\xi \), one can evaluate the influence of this parameter on the observable effects. With this purpose we calculate the lowest electron-hole pair energies as a function of \( c_\xi \) for
all QDH’s under consideration (see Fig. 10). It is seen from Fig. 10 that when the parameter $c_{j}$ changes from $2$ to $2$, the corresponding energy differences $E_{c_{j}}(c_{j}=2) - E_{c_{j}}(c_{j}=-2)$ constitute $-175$ meV for HgS/CdS ($a=2$ nm), $-15$ meV for InAs/GaAs ($a=4$ nm), and $20$ meV for GaAs/AlAs ($a=3$ nm). These differences should be quite accessible for experimental detection.

VI. CONCLUSIONS

The exact nonsymmetrized eight-band effective-mass Hamiltonian for an arbitrary three-dimensional heterostructure has been obtained using Burt’s envelope-function repre-
The 2\times 2 electron and 6\times 6 hole energy-dependent Hamiltonians have been deduced. Within the spherical approximation, the 8\times 8, 2\times 2, and 6\times 6 radial Hamiltonians and the necessary BC’s have been derived for spherical QDH’s. The boundary conditions for radial symmetrized and nonsymmetrized Hamiltonians are different and lead therefore to different energy levels and wave functions. We have shown, further, that the CR’s, which are commonly used to match the solutions of the appropriate bulk \( k \cdot p \) Hamiltonians, coincide with BC’s for the symmetrized Hamiltonians. A theoretical estimate for the value of the spin-orbit splitting of electron levels has been found. The energy levels of the nonsymmetrized eight-band Hamiltonian have been calculated as a function of the dot radius for three spherical QDH’s: a zero-gap semiconductor embedded into a wide-gap semiconductor \( \text{HgS/CdS} \), a narrow-gap semiconductor embedded into a medium-gap semiconductor \( \text{InAs/GaAs} \), and a medium-gap semiconductor embedded into a wide-gap semiconductor \( \text{GaAs/AlAs} \). It has been demonstrated that parameters of dissymmetry \( \chi(r) \) and \( \xi(r) \), giving nonzero contributions to the multiband Hamiltonians only at the heterointerfaces, have, nevertheless, a strong effect on the electron and hole spectra. Thus, for practically important cases of relatively small QDH’s with noticeably different effective-mass parameters of the constituent materials, the use of the obtained Hamiltonian is necessary for the adequate description of experiment. Using the method developed in the present paper, electron and hole states are studied in \( \text{CdS/HgS/CdS/H}_2\text{O} \) and \( \text{CdTe/HgTe/CdTe/H}_2\text{O} \) quantum dot quantum-well heterostructures [E. P. Pokatilov et al., Phys. Rev. B 64, 245329 (2001)].

FIG. 7. \( S \)-type radial components of the wave functions of the electron and hole ground states in the \( \text{HgS/CdS} \) QDH (radius \( a = 2 \) nm) within the nonsymmetrized eight-band model. Solid and dashed lines denote the cases \( c_\xi = 1 \) and \( c_\xi = -1 \), correspondingly, while grey bands represent the continuous change of \( c_\xi \) within these limits. Each radial wave function is normalized by unity, i.e., the integral probability \( \sum_\mu \int_0^a \! r^2 R_\mu^2(r) \, dr = 1 \), where \( \mu \) labels the radial components. Contributions to the integral probability from the depicted radial components vary from 68.6% to 64.8% for an electron and from 74.3% to 81.1% for a hole when \( c_\xi \) changes from 1 to \(-1\). At the same time the electron energy changes from 533.6 meV to 678.8 meV and the hole energy changes from \(-247.2 \) meV to \(-202.1 \) meV.

FIG. 8. \( S \)-type radial components of the wave functions of the electron and hole ground states in the \( \text{InAs/GaAs} \) QDH (radius \( a = 4 \) nm) within the nonsymmetrized eight-band model. Normalization of each radial wave function and denotations are same as in Fig. 7. Contributions to the integral probability from the depicted radial components vary from 80.6% to 79.2% for an electron and from 75.3% to 78.7% for a hole when \( c_\xi \) changes from 1 to \(-1\). At the same time the electron energy changes from 736.0 meV to 757.1 meV and the hole energy changes from \(-73.6 \) meV to \(-68.2 \) meV.

FIG. 9. \( S \)-type radial components of the wave functions of the electron and hole ground states in the \( \text{GaAs/AlAs} \) QDH (radius \( a = 3 \) nm) within the nonsymmetrized eight-band model. Normalization of each radial wave function and denotations are the same as in Fig. 7. Contributions to the integral probability from the depicted radial components vary from 85.4% to 86.9% for an electron and from 88.9% to 86.6% for a hole when \( c_\xi \) changes from 1 to \(-1\). At the same time the electron energy changes from 1880.4 meV to 1850.4 meV and the hole energy changes from \(-111.6 \) meV to \(-122.9 \) meV.

FIG. 10. The lowest electron-hole pair energies in different QDH’s as a function of \( c_\xi \) (\( \chi \neq 0 \)). Each dot is related to the closest curve and indicates the corresponding result of the symmetrized model (\( c_\xi = 0, \chi = 0 \)).

APPENDIX A: INTERBAND MOMENTUM MATRIX ELEMENTS

Using the general effective-mass equations [Eq. (6.3) of Ref. 19], one can see the origin of the interband momentum matrix elements $v_1(r)$ and $v_2(r)$ from Eq. (1):

$$v_1(E,r) = -\frac{4i}{\hbar} \langle S|\hat{p}_z|Z\rangle - \frac{4i}{\hbar} \sum_{v} \left[E - H_{vv}(r)\right]^{-1} H_{Sv}(r) \times \langle v|\hat{p}_z|Z\rangle;$$

(A1)

$$v_2(E,r) = -\frac{4i}{\hbar} \sum_{v} \left[E - H_{vv}(r)\right]^{-1} \langle S|\hat{p}_z|v\rangle H_{vZ}(r).$$

(A2)

To obtain Eqs. (A1) and (A2) it should be taken into account that within the developed eight-band approach the conduction band with the Bloch function $|S\rangle$ and the valence band with the Bloch functions $|X\rangle$, $|Y\rangle$, and $|Z\rangle$ are included explicitly, while all other bands with the Bloch functions $|v\rangle$ are considered to be remote. Further, following the technique of Ref. 19 it is necessary to exclude the energy dependence from Eqs. (A1) and (A2) by replacing $E$ with an average energy, for instance the energy at the middle of the narrowest gap for the heterostructure compounds. Parameters $v_1(r)$ and $v_2(r)$ are approximately considered to be constant in each layer of a heterostructure.

In bulk, if Burt’s material-independent basis functions coincide with the bulk Bloch functions, the second terms in the right-hand side of Eq. (A1) and the right-hand side of Eq. (A2) vanish, because in this case $H_{Sv}(r) = 0$ and $H_{vZ}(r) = 0$. Therefore, one obtains $v_1 = 2u$ ($v = -2i\langle S|\hat{p}_z|Z\rangle/\hbar$) and $v_2 = 0$, which results in $c_\xi = u$ [see Eq. (2)] and $c_\xi = 1$ [see Eq. (8)]. When materials constituting the heterostructure have close parameters, the second terms in the right-hand-side of Eq. (A1) and the right-hand-side of Eq. (A2) are small compared with the first term in the right-hand-side of Eq. (A1). In this case $c_\xi$ does not differ significantly from $u$, and $c_\xi$ is close to 1. In a general case of disparate materials, $c_\xi$ can take arbitrary values.

APPENDIX B: ENERGY-DEPENDENT SEPARATE HAMILTONIANS FOR ELECTRONS AND HOLES

For narrow-gap semiconductors, the accurate way to take into account the coupling of conduction and valence bands is to consider the eight-band Hamiltonian. However, sometimes it is easier to solve a CB or VB Schrödinger equation with energy-dependent effective-mass parameters. Solutions of these equations are just an approximation to the results of the eight-band model. In what follows, we deduce the $2 \times 2$ energy-dependent Hamiltonian for an electron and the $6 \times 6$ energy-dependent Hamiltonian for a hole from the exact eight-band nonsymmetrized effective-mass Hamiltonian.

1. $2 \times 2$ energy-dependent Hamiltonian for an electron

a. Nonsymmetrized CB Hamiltonian

We start with the nonsymmetrized eight-band Hamiltonian $\hat{H}$ defined by Eq. (12). The wave function $\Psi$, i.e., a vector of eight envelope functions $\Psi_1, \ldots, \Psi_8$ is an eigenfunction of the matrix Schrödinger equation

$$\hat{H}\Psi = E\Psi,$$

(B1)

where $E$ is an eigenenergy. To find the CB Hamiltonian, one should treat all VB’s as remote. Therefore, we should exclude all VB envelopes, i.e., $\Psi_3, \ldots, \Psi_8$, from Eq. (B1). As seen, this exclusion is possible only within the approximations $\gamma_1 = 0$, $\gamma_2 = 0$, and $\gamma_3 = 0$, in other words, when the contributions to the hole effective-mass parameters from the remote bands (all bands except two CB’s and six VB’s) are negligible. This is a very close approximation, because the parameters $\gamma_1, \gamma_2$, and $\gamma_3$ are small for almost all materials and, determining contributions to the VB, they certainly have small influence on the electron levels. Under this approximation $\chi = -1/3$ [see Eq. (7)] and it cancels from the Hamiltonian. Another necessary approximation is $c_\xi = 1$, i.e., $\xi = -v$, and therefore $v_1 = 0, v_2 = 2v$ [see Eqs. (8) and (2)]. This is the only approximation that does not lead to the discontinuity of CB envelopes $\Psi_1$ and $\Psi_2$ at the heterointerface. Now we can express six VB envelopes $\Psi_3, \ldots, \Psi_8$ in terms of two CB envelopes $\Psi_1$ and $\Psi_2$ using the last six equations of the set (B1). This procedure results in

$$\Psi_3 = -i\frac{v}{E - E_v} \hat{k}_- \Psi_1,$$

$$\Psi_4 = \frac{v}{E - E_v} \left(\sqrt{\frac{2}{3}} \hat{k}_- \Psi_1 - \frac{1}{\sqrt{3}} \hat{k}_- \Psi_2\right),$$

$$\Psi_5 = \frac{v}{E - E_v} \left(-i\frac{1}{\sqrt{3}} \hat{k}_+ \Psi_1 - i\sqrt{\frac{2}{3}} \hat{k}_+ \Psi_2\right),$$

$$\Psi_6 = -i\frac{v}{E - E_v} \hat{k}_- \Psi_2,$$

$$\Psi_7 = \frac{v}{E - E_v + \delta} \left(-i\frac{1}{\sqrt{3}} \hat{k}_- \Psi_1 - i\sqrt{\frac{2}{3}} \hat{k}_- \Psi_2\right),$$

(B2)

$$\Psi_8 = \frac{v}{E - E_v + \delta} \left(\sqrt{\frac{2}{3}} \hat{k}_+ \Psi_1 - \frac{1}{\sqrt{3}} \hat{k}_+ \Psi_2\right),$$

where $\epsilon = 2m_0E/\hbar^2$. Substituting the envelopes (B2) into the first two equations of the set (B1), one obtains the sought-after CB Hamiltonian for the electron envelopes $\Psi_1$ and $\Psi_2$. This Hamiltonian has the form

$$\hat{H}_e = \frac{\hbar^2}{2m_0} \begin{pmatrix} \epsilon_e + P_e & C_e \\ C_e^\dagger & \epsilon_e + P_e \end{pmatrix},$$

(B3)
where

$$P_e = \hat{k}_+ \left( \frac{m_0}{m_c(\varepsilon)} + g_c(\varepsilon) \right) \hat{k}_+ + \hat{k}_- \left( \frac{m_0}{m_c(\varepsilon)} - g_c(\varepsilon) \right) \hat{k}_-.$$ 

$$C_\varepsilon = - \sqrt{2}(\hat{k}_+ g_c(\varepsilon) \hat{k}_+ - \hat{k}_- g_c(\varepsilon) \hat{k}_-), \tag{B4}$$

$$\frac{m_0}{m_c(\varepsilon)} = \alpha + \frac{v^2}{3} \left( \frac{2}{\varepsilon - \varepsilon_v} + \frac{1}{\varepsilon - \varepsilon_v + \delta} \right),$$

$$g_c(\varepsilon) = \frac{v^2}{3} \left( \frac{1}{\varepsilon - \varepsilon_v} - \frac{1}{\varepsilon - \varepsilon_v + \delta} \right). \tag{B5}$$

Here, $m_0/m_c(\varepsilon)$ is the inverse of the energy-dependent effective mass of an electron, and $g_c(\varepsilon)$ is an energy-dependent interfacial parameter, which vanishes when the spin-orbit splitting $\delta$ is zero. Like $\chi$, this parameter gives a nonzero contribution to the Hamiltonian only at the heterointerface. The parameter $g_c(\varepsilon)$ is responsible for the non-symmetrical form of the Hamiltonian (B3) and for the mixing of the envelopes $\Psi_1$ and $\Psi_2$. When one solves the Schrödinger equation for an electron using the energy-dependent Hamiltonian (B3), one finds the eigenenergy $E$ and eigenfunctions $\Psi_1$ and $\Psi_2$. Then, substituting these eigenfunctions into Eq. (B2), one obtains the rest envelopes $\Psi_3, \ldots, \Psi_8$, and therefore $\Psi$. While the functions $\Psi_1$ and $\Psi_2$ are continuous at the heterointerface, the functions $\Psi_3, \ldots, \Psi_8$, like the envelope functions of all the other remote bands, are not. Note that only the wave functions $\Psi$, i.e., vectors of eight envelope functions $\Psi_1, \ldots, \Psi_8$, are orthonormalized. The envelopes $\Psi_1$ and $\Psi_2$ are neither orthogonal nor properly normalized. When the nonparabolicity is not strong, in other words, when $m_c(\varepsilon)$ only weakly depends on the energy, it is possible to choose one appropriate value of the energy, e.g., $\varepsilon_0$ to find $m_c(\varepsilon_0)$ and $g_c(\varepsilon_0)$, and to substitute them into the Hamiltonian (B3). In such a way one obtains the Hamiltonian $\hat{H}_c(\varepsilon_0)$. The eigenfunctions $\Psi_1$ and $\Psi_2$ of this Hamiltonian will be orthonormalized and the rest of the six envelopes will be no longer needed.

### b. CB Hamiltonians and BC’s for a spherical QDH

The radial CB Hamiltonian $\hat{H}_{c,j}^{(p)}$ for spherical QDH’s can be derived from the Hamiltonian (B3) by the same way as the radial Hamiltonian (24) has been obtained from the Hamiltonian (12) in the spherical approximation (see Sec. III). Thus we find

$$\hat{H}_{c,j}^{(p)} = \frac{\hbar^2}{2m_0}(\varepsilon_c - \tau_{c,j}^{(p)} - \Delta_{l}^{(p)}), \tag{B6}$$

where

$$\tau_{c,j}^{(p)} = \frac{(l+1)\Delta_{l}^{(1)}}{2l+1} \left( \frac{m_0}{m_c(\varepsilon)} + g_c(\varepsilon) \right) + l\Delta_{l}^{(-1)} \left( \frac{m_0}{m_c(\varepsilon)} + g_c(\varepsilon) \right) - \Delta_{l}^{(p)} \left[ g_c(\varepsilon) \right] \tag{B7}$$

and the operator $\Delta_{l}^{(p)}(\beta)$ is defined by Eq. (26). Inside the $i$th spherical layer, the Hamiltonian (B6) takes the form

$$\hat{H}_{c,j}^{(p)} = \frac{\hbar^2}{2m_0}(\varepsilon_c - \frac{m_0}{m_{c,i}(\varepsilon)} \Delta_{l}^{(p)}), \tag{B8}$$

where $\Delta_{l}$ is the spherical Laplacian and $m_{c,i}(\varepsilon)$ is the energy-dependent CB mass of the $i$th material. Further, one should solve the Schrödinger equation with the Hamiltonian (B8) for each spherical layer and match the obtained solutions at the spherical heterointerfaces using the BC’s (31) (see Sec. IV). The radial component of the CB current operator $\hat{J}_{c,j}^{(p)}$ is obtained from the Hamiltonian (B6) in the same way the radial component of the current operator (32) has been obtained from the Hamiltonian (24). Thus,

$$\hat{J}_{c,j}^{(p)} = \frac{i\hbar}{m_0} \left( - \frac{m_0}{m_c(\varepsilon)} \frac{\partial}{\partial r} - p(j+1/2-p) \frac{g_c(\varepsilon)}{r} \right). \tag{B9}$$

In a two-layer spherical QDH the electron energy depends on the difference $g_{c,1}(\varepsilon) - g_{c,2}(\varepsilon)$ [as seen from the BC’s (31) and (B9)], where the indices “1” and “2” denote the interior and exterior materials, correspondingly. The value of this difference is usually very small for typical QDH’s. Therefore, in the first approximation, one can find the energy spectrum $E_l \ (l = j + p/2)$ neglecting the term proportional to $p(j + 1/2 - p)[g_{c,1}(\varepsilon) - g_{c,2}(\varepsilon)]$ in the BC’s. Then, including this term as a perturbation, one finds the energy spectrum $E_{l'}$. It is seen that the energy levels with $l = 0$ remain unchanged, while each energy level $E_l$ with $l \neq 1$ splits into two levels: $E_{l'}^{1/2}$ and $E_{l'}^{-1/2}$. For the electron levels that are not very close to the CB minimum (as is the case for the QDH’s under consideration), the following estimate can be obtained:

$$E_{l'} = \frac{(l+1)E_{l'}^{1/2} + lE_{l'}^{-1/2}}{2l+1},$$

$$E_{l'}^{1/2} - E_{l'}^{-1/2} = \frac{\hbar^2(2l-1)}{m_0a^2} [g_{c,1}(\varepsilon_l) - g_{c,2}(\varepsilon_l)], \tag{B10}$$

where $\varepsilon_l = 2m_0E_l/\hbar^2$. In Table III we have used Eq. (B10) to estimate the spin-orbit splitting of the lowest $P$ and $D$ levels.
It is seen that the value of the splitting of the electron levels is of the order of 3 meV in all considered QDH’s, and therefore this splitting can be neglected. This fact does not imply that the dependence of the parameters of the CB Hamiltonian on the energy can be neglected, too. As seen from Table III, the electron effective masses in QDH’s can differ by a factor of 2 from their values in the corresponding bulk materials.

2. 6×6 energy-dependent Hamiltonian for a hole

a. Nonsymmetrized VB Hamiltonian

The deduction of the VB Hamiltonian is analogous to the deduction of the CB Hamiltonian with only one difference: one should treat two CB’s as remote. In order to express the CB envelopes Ψ₁ and Ψ₂ in terms of the VB envelopes Ψ₃,...,Ψ₈ and to exclude them from the Schrödinger equation (B1), one should apply the approximation α=0 and ε₁=1. This approximation has the same grounds as the approximation used above to obtain the CB Hamiltonian. Now, we express the CB envelopes Ψ₁ and Ψ₂ in terms of the VB envelopes Ψ₃,...,Ψ₈ from the first two equations of the set (B1) and substitute them into the last six equations of the same set. As a result we have the VB Hamiltonian $\hat{H}_h$, which coincides with the Hamiltonian $\hat{H}$ [see Eq. (12)] where the first two rows and the first two columns are deleted and the effective-mass parameters are changed in the following way:

$$\gamma_1 \rightarrow \gamma_1^G(\varepsilon) = \gamma_1 + \frac{v^2}{3(\varepsilon_c - \varepsilon)},$$  
$$\gamma_{2,3} \rightarrow \gamma_{2,3}^L(\varepsilon) = \gamma_{2,3} + \frac{v^2}{6(\varepsilon_c - \varepsilon)}. \quad (B11)$$

Here, $\gamma_j^G(\varepsilon)$ are the energy-dependent Luttinger parameters. In conformity with Eq. (7), one should change the parameter of dissymmetry $\chi$ as follows:

$$\chi \rightarrow \chi^L(\varepsilon) = \chi + \frac{v^2}{6(\varepsilon_c - \varepsilon)}. \quad (B12)$$

As a result of the change (B12), the parameter of dissymmetry increases (see Table III), therefore the results of the symmetrized Hamiltonian (with $\chi^L=0$) will deviate sharply from the exact solutions. The parameters $\gamma_j^L$ usually weakly depend on the energy. Consequently, to obtain the hole spectrum one can use the Hamiltonian $\hat{H}_h(\varepsilon_0)$, where $\varepsilon_0$ is an average hole energy.

b. VB Hamiltonian and BC’s for a spherical QDH

The radial VB Hamiltonian $\hat{H}_{h0}^{(p)}$ for a spherical QDH coincides with the radial Hamiltonian (24) in which $\gamma_1 \rightarrow \gamma_1^G(\varepsilon)$ and $\chi \rightarrow \chi^L(\varepsilon)$ [in conformity with Eqs. (B11) and (B12)], $\gamma_j \rightarrow \gamma_j^L(\varepsilon) = \gamma_j + \frac{v^2}{6(\varepsilon_c - \varepsilon)}$ [in conformity with Eqs. (B11) and (14)] and where the first two rows and the first two columns are deleted. For the radial components of the hole wave function one should use the BC’s (31), in which the radial component of the current operator $J_{h0}^{(p)}$ is given by the matrix (32) where the first row and the first column are deleted and the parameters $\gamma_1$, $\gamma$, and $\chi$ are replaced by the parameters $\gamma_1^G$, $\gamma^L$, and $\chi^L$, correspondingly.
