We prove an upper bound for the convergence rate of the homogenization limit $\epsilon \to 0$ for a linear transmission problem for a advection-diffusion(-reaction) system posed in areas with low and high diffusivity, where $\epsilon$ is a suitable scale parameter. On this way, we justify the formal homogenization asymptotics obtained by us earlier by proving an upper bound for the convergence rate (a corrector estimate). The main ingredients of the proof of the corrector estimate include integral estimates for rapidly oscillating functions with prescribed average, properties of the macroscopic reconstruction operators, energy bounds and extra two-scale regularity estimates. The whole procedure essentially relies on a good understanding of the analysis of the limit two-scale problem.

Keywords: Corrector estimates, transmission condition, homogenization, micro-macro transport, reaction-diffusion system in heterogeneous materials

MSC 2010: 35B27; 35K57; 76S05

1 Introduction

We study the averaging of a system of reaction-diffusion equations with linear transmission condition posed in a class of highly heterogeneous media including areas of low and high diffusivity. Our aim is twofold: on one hand, we wish to justify rigorously the formal asymptotics expansions performed in [30], while on the other hand we wish to understand the error caused by replacing a heterogeneous solution by an approximation (averaged) estimate. To this end, we prove an upper bound for the convergence rate of the limit procedure $\epsilon \to 0$, where $\epsilon$ is a suitable scale parameter (see section 2.1 for the definition of $\epsilon$). The materials science scenario we have in view is motivated by a very practical problem: the sulfate corrosion of concrete. We refer the reader to [3] for a nice and detailed description of the physico-chemical scenario and to [17] for the formal (two-scale) averaging of locally-periodic distributions of unsaturated pores attacked by sulphuric acid. The reference [18] contains the rigorous proof of the limiting procedure $\epsilon \to 0$ treating the uniformly periodic case of the same corrosion scenario. In [18], the
main working tools involve the two-scale convergence concept in the sense of Nguetseng and Allaire\(^1\) combined with a periodic unfolding of the oscillatory boundary. Here, we use an energy-type method.

The framework that we tackle in this context is essentially a deterministic one. We assume that a distribution of the \textit{locally-periodic array of microstructures}\(^2\) is known \textit{a priori}. We refer the reader to [6] for related discussion of continuum mechanical descriptions of balance laws in continua with microstructure. At the mathematical level, we succeed to combine successfully the philosophy of getting correctors as explained in the analysis by Chechkin and Piatnitski [7] with the intimate two-scale structure of our system; see also [8, 9] for related settings where similar averaging strategies are used. For methodological hints on how to get corrector estimates, we refer the reader to the analysis shown in [14] for the case of a reaction-diffusion phase field-like system posed in fixed domains.

For a higher level of discussion, see the monograph [10] which is a nicely written introductory text on homogenization methods and applications. It is worth noting that the periodic homogenization of linear transmission problems is a well-understood subject (cf. [1, 15, 19, 28], e.g.), however much less is known if one steps away from the periodic setting even if one stays within the deterministic case. If the microstructures are distributed in a suitable random fashion, then concepts like random fields (see [4] or [5] and references cited therein; [21] and intimate connection with the stochastic geometry of the perforations) can turn to be helpful to getting averaged equations (eventually also capturing new memory terms), but corrector estimates seem to be very hard to get; cf., e.g., [2]. Disordered media for which the stationarity and/or ergodicity assumptions on the random measure do not hold or situations where at a given time scale length scales are non-separated are typical situations that cannot be averaged with existing techniques (so it makes no sense to search here for correctors).

This paper is organized as follows: In Section 2 we introduce the necessary notation, the microscale and the two-scale limit model. Section 3 contains the main result of our paper – Theorem 3.1. In Section 4 we introduce the technical assumptions needed to obtain the correctors. At this point, we also collect the known well-posedness and regularity results for both the microscopic model and the two-scale limit model. The rest of the paper consists of the proof of the convergence rate and is the subject of Section 5.

2 Statement of the problem

In this section we introduce our notation, the microscale model and the two-scale limit problem. We start off with the definition of the locally periodic heterogeneous medium.

\(^1\) For an introduction to two-scale convergence, see [23].

\(^2\) Here, we deviate from the purely periodic setting. It is worth noting also that the assumption of statistically homogeneity of distribution of microstructures, which is a crucial restriction of stochastic homogenization, does not cover all possible configurations of locally-periodic geometries. Also, as we formulate the working framework, we cannot treat neither randomly placed microstructures nor stochastic distributions of microgeometries. Consequently, the exact connection between these two averaging techniques is hard to make precise.
2.1 Definition of the locally-periodic micro medium

We consider a heterogeneous medium consisting of areas of high and low diffusivity. The medium is in the present paper represented by a two dimensional domain. For the definition of the locally-periodic medium with inclusions, we follow in main lines [7]. We denote the two dimensional bounded domain by $\Omega \subset \mathbb{R}^2$, with boundary $\Gamma$. Denote

$$J_\epsilon := \{ j \in \mathbb{Z}^2 | \text{dist}(\epsilon j, \Gamma) \geq \epsilon \sqrt{2} \},$$

$$U := \{ y \in \mathbb{R}^2 \mid -1/2 \leq y_i \leq 1/2 \text{ for } i = 1, 2 \}.$$

A convenient way to parameterize the interface $\Gamma_\epsilon$ between the high and low diffusivity areas, is to use a level set function, which we denote by $S_\epsilon(x)$:

$$x \in \Gamma_\epsilon \Leftrightarrow S_\epsilon(x) = 0,$$

Since we allow the size and shape of the perforations to vary with the macroscopic variable $x$, we use the following characterization of $S_\epsilon$:

$$S_\epsilon(x) := S(x, x/\epsilon), \quad (2.1)$$

where $S : \Omega \times U \to \mathbb{R}$ is 1-periodic in its second variable, and where $S$ is independent of $\epsilon$. We assume that $S(x, 0) < \text{const.} < 0$ and $S(x, y)_{y \in \partial U} > \text{const.} > 0$ for all $x \in \Omega$, so that the areas of low diffusivity in each unit cell do not touch each other. We set

$$Q_\epsilon^j := \{ x \in \epsilon(U + j) \mid S(x, x/\epsilon) < 0 \},$$
and introduce the area of low diffusivity $\Omega_\epsilon^l$ as follows:

$$\Omega_\epsilon^l := \bigcup_{j \in J^*} Q_{\epsilon}^j,$$

and the area of high diffusivity $\Omega_\epsilon^h$ as:

$$\Omega_\epsilon^h := \Omega \setminus \Omega_\epsilon^l.$$

We call a medium of which the geometry is specified with a level set function of the type that is given in (2.1) a locally periodic medium [7]. In Fig. 1 a schematic picture is given of how such a medium might look like for a given $\epsilon > 0$. Note that by construction the area of high diffusivity $\Omega_\epsilon^h$ is connected and the area of low diffusivity $\Omega_\epsilon^l$ is disconnected.

The interface between high and low diffusivity areas $\Gamma_\epsilon$ is now given by $\Gamma_\epsilon = \partial \Omega_\epsilon^l$ and the boundary of $\Omega_\epsilon^h$ is given by $\partial \Omega_\epsilon^h = \Gamma_\epsilon \cup \Gamma$.

Furthermore, we use the notation $\Omega_\epsilon^l := \Omega \setminus \bigcup_{j \in J^*} (\epsilon (U + j))$, and we introduce for later use the smooth cut-off function $\chi_\epsilon(x)$ that satisfies $0 \leq \chi_\epsilon(x) \leq 1$, $\chi_\epsilon(x) = 0$ if $x \in \Omega_\epsilon^l$ and $\chi_\epsilon(x) = 1$ if $\text{dist}(x, \Omega_\epsilon^l) \geq \text{dist}(\Gamma_\epsilon, \Omega_\epsilon^l)$. Moreover, $\epsilon \| \nabla \chi_\epsilon \| \leq C$ and $\epsilon^2 \| \Delta \chi_\epsilon \| \leq C$, with $C$ independent of $\epsilon$, and also

$$\| 1 - \chi_\epsilon \|_{L^2(\Omega)} \leq \epsilon^{1/2} C, \quad \| \nabla \chi_\epsilon \|_{L^2(\Omega)} \leq \epsilon^{-1/2} C, \quad \| \Delta \chi_\epsilon \|_{L^2(\Omega)} \leq \epsilon^{-3/2} C,$$

with $C$ again independent of $\epsilon$ (see e.g. [7, 14]).

In addition, we need to expand the normal $\nu_\epsilon$ to $\Gamma_\epsilon$ in a power series in $\epsilon$. This can be done in terms of the level set function $S_\epsilon$, which we assume to be sufficiently regular so that all the following computations make sense (see assumption (B1) in section 4):

$$\nu_\epsilon = \frac{\nabla S_\epsilon(x)}{\| \nabla S_\epsilon(x) \|} = \frac{\nabla S(x, x/\epsilon)}{\| \nabla S(x, x/\epsilon) \|} = \frac{\nabla_x S + \frac{1}{\epsilon} \nabla_y S}{\| \nabla_x S + \frac{1}{\epsilon} \nabla_y S \|} \quad \text{at} \quad x \in \Gamma_\epsilon. \quad (2.3)$$

First we expand $\| \nabla S_\epsilon \|$. Using the Taylor series of the square-root function, we obtain

$$\| \nabla S_\epsilon \| = \frac{1}{\epsilon} \| \nabla_y S \| + O(\epsilon^0). \quad (2.4)$$

In the same fashion, we get

$$\nu_\epsilon = \nu_0 + \epsilon \nu_1 + O(\epsilon^2),$$

where

$$\nu_0 := \frac{\nabla_y S}{\| \nabla_y S \|}$$

and

$$\nu_1 := \frac{\nabla_x S}{\| \nabla_y S \|} - \frac{(\nabla_x S \cdot \nabla_y S)}{\| \nabla_y S \|^2} \frac{\nabla_y S}{\| \nabla_y S \|}. \quad (2.5)$$

If we introduce the normalized tangential vector $\tau_0$, with $\tau_0 \perp \nu_0$, we can rewrite $\nu_1$ as

$$\nu_1 = \frac{\tau_0 \cdot (\nabla_x S)}{\| \nabla_y S \|}. \quad (2.6)$$
Later on we will also use the notation
\[ \nu_1^\epsilon = \epsilon^{-1}(\nu^\epsilon - \nu_0) = \nu_1 + O(\epsilon). \]

### 2.2 Microscopic equations and their upscaled form

We focus on the following microscopic model
\[
\begin{aligned}
\partial_t u_\epsilon &= \nabla \cdot (D_h \nabla u_\epsilon - q_\epsilon u_\epsilon) \quad \text{in } \Omega_h^\epsilon, \\
\partial_t v_\epsilon &= \epsilon^2 \nabla \cdot (D_l \nabla v_\epsilon) \quad \text{in } \Omega_l^\epsilon, \\
\nu^\epsilon \cdot (D_h \nabla u_\epsilon) &= \epsilon^2 \nu^\epsilon \cdot (D_l \nabla v_\epsilon) \quad \text{on } \Gamma^\epsilon, \\
u_\epsilon &= v_\epsilon \quad \text{on } \Gamma, \\
u_\epsilon(x,t) &= u_b(x,t) \quad \text{on } \Gamma, \\
u_\epsilon(x,0) &= u_I^\epsilon(x) \quad \text{in } \Omega_h^\epsilon, \\
v_\epsilon(x,0) &= v_I^\epsilon(x) \quad \text{in } \Omega_l^\epsilon.
\end{aligned}
\]

Here we denoted the tracer concentration in the high diffusivity area by \( u_\epsilon \), the concentration in the low diffusivity area by \( v_\epsilon \), and the velocity of the fluid phase by \( q_\epsilon \). Furthermore, \( D_h \) denotes the diffusion coefficient in the high diffusivity region, \( D_l \) the diffusion coefficient in the low diffusivity regions, \( \nu^\epsilon \) denotes the unit normal to the boundary \( \Gamma^\epsilon(t) \), where \( u_b \) denotes the Dirichlet boundary data for the concentration \( u^\epsilon \), and where \( u_I^\epsilon \) and \( v_I^\epsilon \) are the initial values for the active concentrations \( u_\epsilon \) and \( v_\epsilon \), respectively.

In order to formulate the upscaled equations and obtain closed-formulae for the effective transport coefficients, we use the notations
\[
B(x) := \{ y \in \mathcal{U} : S(x,y) < 0 \},
\]
and
\[
Y(x) := \mathcal{U} - B(x),
\]
and we define the following \( x \)-dependent cell problem:\footnote{See, e.g. [11, 22], for the role of cell problems in formulating averaged equations.}
\[
\begin{aligned}
\Delta_y M_j(x,y) &= 0 \quad \text{for all } x \in \Omega, y \in Y(x), \\
\nu_0 \cdot \nabla_y M_j(x,y) &= -\nu_0 \cdot e_j \quad \text{for all } x \in \Omega, y \in \partial B(x), \\
M_j(x,y) &= y\text{-periodic},
\end{aligned}
\]
for \( j \in \{1,2\} \). To ensure the uniqueness of weak solutions to this cell problem, suitable conditions on the spatial averages of the cell functions need to be added.

The solution to this cell problems allows us to write the results of the formal homogenization procedure in the form of the following distributed-microstructure (two-scale)
Adrian Muntean and Tycho van Noorden

model

\[
\begin{align*}
\partial_t v_0(x,y,t) &= D_l \Delta_y v_0(x,y,t) \quad \text{for } y \in B(x), \ x \in \Omega, \\
\partial_t \left( \theta(x) u_0 + \int_{|y|<r(x)} v_0 \ dy \right) &= \nabla_x \cdot (\mathcal{D}(x) \nabla_x u_0 - \bar{q} u_0) \quad \text{for } x \in \Omega, \\
v_0(x,y,t) &= u_0(x,t) \quad \text{for } y \in \partial B(x), \\
u_0(x,t) &= u_b(x,t) \quad \text{for } x \in \Gamma, \\
u_0(x,y,0) &= v_I(x,y) \quad \text{for } y \in B(x), \ x \in \Omega.
\end{align*}
\] (2.15)

\[
\begin{align*}
v_0(x,y,t) &= u_0(x,y,t) \quad \text{for } y \in \partial B(x), \\
u_0(x,t) &= u_b(x,t) \quad \text{for } x \in \Gamma, \\
u_0(x,y,0) &= v_I(x,y) \quad \text{for } y \in B(x), \ x \in \Omega.
\end{align*}
\] (2.16)

where the porosity \( \theta(x) \) of the medium is given by

\[
\theta(x) := |Y(x)| = 1 - |B(x)|,
\]

and where the effective diffusivity tensor \( \mathcal{D}(x) \) is defined by

\[
\mathcal{D}(x) := D_h \int_{Y(x)} (I + \nabla_y M(x,y)) \ dy,
\]

with \( M = (M_1, M_2) \).

3 Main result

Recall that \((u_\epsilon, v_\epsilon)\) is the solution vector for the micro problem and \((u_0, v_0)\) is the solution vector for the two-scale problem. We introduce now the macroscopic reconstructions\(^4\) \(u_0^\epsilon, v_0^\epsilon, u_1^\epsilon\), which are defined as follows

\[
\begin{align*}
u_0^\epsilon(x,t) &= u_0(x,t) \quad \text{for all } x \in \Omega_h^\epsilon, \\
v_0^\epsilon(x,t) &= v_0(x,x/\epsilon,t) \quad \text{for all } x \in \Omega_l^\epsilon, \\
u_1^\epsilon(x,t) &= u_0^\epsilon(x,t) + \epsilon M(x,x/\epsilon) \nabla u_0^\epsilon(x,t) \quad \text{for all } x \in \Omega_h^\epsilon.
\end{align*}
\] (3.1-3.3)

In the same spirit, we introduce the reconstructed flow velocity \(q_0^\epsilon(x) = q(x)\) for all \( x \in \Omega_h^\epsilon \) and the corresponding reconstructions \(u_0^\epsilon, v_0^\epsilon\) for the macroscopic initial data \(u_I\) and \(v_I\), respectively.

The main result of our paper is stated in the next Theorem. The applicability of this result confines to our working assumptions (A1), (A2), (B1), (B2), and (B3) that we introduce in Section 4.

\textbf{Theorem 3.1} Assume (A1), (A2), (B1), (B2), and (B3). Then the following convergence rate holds

\[
\begin{align*}
||u_k - u_0^\epsilon||_{L^\infty(I,L^2(\Omega_h^\epsilon))} + ||u_k - v_0^\epsilon||_{L^\infty(I,L^2(\Omega_l^\epsilon))} + \\
||u_k - u_1^\epsilon||_{L^\infty(I,H^1(\Omega_h^\epsilon))} + \epsilon||v_k - v_0^\epsilon||_{L^\infty(I,H^1(\Omega_l^\epsilon))} &\leq c \sqrt{\epsilon},
\end{align*}
\] (3.4)

where \(I = (0,T]\), and where the constant \(c\) is independent of \(\epsilon\).

\(^4\) We borrowed this terminology from [14]. Note however that the concept of reconstruction operators appears in various other frameworks like for the heterogeneous multiscale method [13].
The remainder of the paper is concerned with the proof of Theorem 3.1.

4 Technical preliminaries

4.1 Function Spaces. Assumptions. Known results

4.1.1 Functional setting

As space of test functions for the microscopic problem, we take the Sobolev space
\[ H^1(\Omega; \partial\Omega) := \{ \varphi \in H^1(\Omega_\epsilon) \text{ with } \varphi = 0 \text{ at } \partial\Omega \}. \]

Since the formulation of the upscaled problem involves two distinct spatial variables \( x \in \Omega \) and \( y \in B(x) \) (with \( B(x) \subset \Omega \)), we need to introduce the following spaces:
\[ V_1 := H^1_0(\Omega), \quad (4.1) \]
\[ V_2 := L^2(\Omega; H^2(B(x))), \quad (4.2) \]
\[ H_1 := L^2(\Omega), \quad (4.3) \]
\[ H_2 := L^2(\Omega; L^2(B(x))). \quad (4.4) \]

The spaces \( H_2 \) and \( V_2 \) make sense, for instance, as indicated in [26].

4.1.2 Assumptions for the microscopic model

**Assumption (A1):** We assume the following restrictions on data and parameters: Take \( D_h, D_l \in [0, \infty], \ u_\epsilon^I \in H^1(\Omega_\epsilon^h), \ v_\epsilon^I \in H^1(\Omega_\epsilon^l), \) and \( u_b \in H^1(I; H^3(\Gamma)). \) Furthermore, we assume
\[ \| u_\epsilon^I - u_\epsilon^0 \|_{L^\infty(\Omega_\epsilon^h)} = \mathcal{O}(\epsilon^{\theta_1}) \text{ with } \theta_1 \geq \frac{1}{2} \]
\[ \| v_\epsilon^I - v_\epsilon^0 \|_{L^\infty(\Omega_\epsilon^l)} = \mathcal{O}(\epsilon^{\theta_2}) \text{ with } \theta_2 \geq \frac{1}{2} \]

**Assumption (A2):** \( q_\epsilon \in H^2(\Omega_\epsilon^h; \mathbb{R}^d) \cap L^\infty(\Omega_\epsilon^h; \mathbb{R}^d) \) with \( \nabla \cdot q_\epsilon = 0 \) a.e. in \( \Omega_\epsilon^h. \) Additionally, we assume that
\[ \| q_\epsilon - \bar{q} \|_{L^2(\Omega_\epsilon^h; \mathbb{R}^d)} = \mathcal{O}(\epsilon^{\theta_3}) \text{ with } \theta_3 \geq \frac{1}{2} \]  

**Remark 4.1** If one wishes to replace \( q_\epsilon \) with the stationary Stokes or Navier-Stokes equations, then a few additional things have to be taken into account. One of the most striking facts is that the exponent \( \theta \) arising in (4.5) seems to be restricted to \( \theta_3 = \frac{1}{5}. \) Consequently, this worsens essentially the convergence rate; see, for instance, [24] (Theorem 1) for a discussion of homogenization of the periodic case.

4.1.3 Assumptions for the two-scale model

**Assumption (B1):** The level set function \( S : \Omega \times U \to \mathbb{R} \) is 1-periodic in its second variable and is in \( C^2(\Omega \times U). \)
Adrian Muntean and Tycho van Noorden

Assumption (B2): We assume the following restrictions on data and parameters:

\[
\begin{align*}
\theta, D & \in L^\infty_+ (\Omega) \cap H^2(\Omega), \\
\bar{q} & \in L^2(\Omega; \mathbb{R}^d) \cap L^\infty(\Omega; \mathbb{R}^d) \text{ with } \nabla \cdot \bar{q} = 0 \text{ a.e. in } \Omega, \\
u_b & \in L^\infty(\Omega \times I) \cap H^1(I; H^3(\Gamma)), \\
\partial_t u_b & \leq 0 \text{ a.e. } (x, t) \in \Omega \times I, \\
u_1 & \in L^\infty(\Omega) \cap H_1 \cap H^2(\Omega), \\
v_1(x, \cdot) & \in L^\infty(\bar{B}(x)) \cap H_2 \text{ for a.e. } x \in \overline{\Omega}.
\end{align*}
\]

Assumption (B3):

\[
\begin{align*}
H_1 & := H_0^1(\Omega), \\
H_2 & := L^2(\Omega; H^2(B(x))), \\
V_1 & := H_0^1(\Omega), \\
V_2 & := L^2(\Omega; H^3(B(x))).
\end{align*}
\]

Remark 4.2 Following the lines of [26] and [29], Assumption (B1) implies in particular that the measures \(|\partial B(x)|\) and \(|B(x)|\) are bounded away from zero (uniformly in \(x\)). Consequently, the following direct Hilbert integrals (cf. [12] (part II, chapter 2), e.g.)

\[
\begin{align*}
L^2(\Omega; H^1(B(x))) & := \{ u \in L^2(\Omega; L^2(B(x))) : \nabla_y u \in L^2(\Omega; L^2(B(x))) \} \\
L^2(\Omega; H^1(\partial B(x))) & := \{ u : \Omega \times \partial B(x) \to \mathbb{R} \text{ measurable such that } \int_\Omega \| u(x) \|^2_{L^2(\partial B(x))} < \infty \}
\end{align*}
\]

are well-defined separable Hilbert spaces and, additionally, the distributed trace

\[
\gamma : L^2(\Omega; H^1(B(x))) \to L^2(\Omega; L^2(\partial B(x)))
\]

given by

\[
\gamma u(x, s) := \gamma_x U(x)(s), \quad x \in \Omega, s \in \partial B(x), u \in L^2(\Omega; H^1(B(x)))
\]

is a bounded linear operator. For each fixed \(x \in \Omega\), the map \(\gamma_x\), which is arising in (4.10), is the standard trace operator from \(H^1(B(x))\) to \(L^2(\partial B(x))\). We refer the reader to [25] for more details on the construction of these spaces and to [27] for the definitions of their duals as well as for a less regular condition (compared to (B1)) allowing to define these spaces in the context of a certain class of anisotropic Sobolev spaces.

For convenience, we also introduce the evolution triple \((\mathbb{V}, \mathbb{H}, \mathbb{H}^*)\), where

\[
\mathbb{V} := \{ (\phi, \psi) \in V_1 \times V_2 \mid \phi(x) = \psi(x, y) \text{ for } x \in \Omega, y \in \partial B(x) \},
\]

\[
\mathbb{H} := H_1 \times H_2,
\]

4.1.4 Analysis of microscopic equations

Definition 4.3 Assume (A1), (A2) and (B1). The pair \((u_\epsilon, v_\epsilon)\), with \(u_\epsilon = U_\epsilon + u_b\) and where \((U_\epsilon, v_\epsilon) \in H^2(\Omega^e_\epsilon; \partial \Omega) \times H^2(\Omega^e_\epsilon)\), is a weak solution of the problem \((P_\epsilon)\) if the
Corrector estimates of a locally-periodic scenario

transmission conditions (2.9) are fulfilled and the following identities hold
\[
\int_{\Omega_h} \partial_t (U_\varepsilon + u_b) \phi \, dx + \int_{\Omega_h} (D_h \nabla (U_\varepsilon + u_b) - q_\varepsilon (U_\varepsilon + u_b)) \cdot \nabla \phi \, dx = - \int_{\Gamma_\varepsilon} \nu^\varepsilon \cdot (\varepsilon^2 D_l \nabla v_\varepsilon) \phi \, ds, \tag{4.13}
\]
\[
\int_{\Omega_l} \partial_t v_\psi \, dy \, dx + \int_{\Omega_l} \varepsilon^2 D_l \nabla v_\psi \cdot \nabla \psi \, dx = \int_{\partial \Omega_{l,\varepsilon}} \nu^\varepsilon \cdot (\varepsilon^2 D_l \nabla v_\varepsilon) \psi \, d\sigma \, dx, \tag{4.14}
\]
for all \((\phi, \psi) \in H^1(\Omega_{h,\varepsilon}; \partial \Omega) \times H^1(\Omega_{l,\varepsilon})\) and \(t \in I\).

**Theorem 4.4** Assume (A1), (A2) and (B1). Problem \((P_\varepsilon)\) admits a unique global-in-time weak solution in the sense of Definition 4.3.

**Proof** Since we deal here with a linear transmission problem, the proof of the Theorem can be done with standard techniques (see [16], e.g.). \(\square\)

4.1.5 Analysis of two-scale equations

This section contains basic results concerning the well-posedness of the two-scale problem, which we reformulate here as:

\[
(P) \quad \begin{cases}
\theta(x) \partial_t u_0 - \nabla_x \cdot (D(x) \nabla u_0 - q u_0) = - \int_{\partial B(x)} \nu_{0} \cdot (D_l \nabla_y v_0) \, d\sigma & \text{in } \Omega, \\
\partial_t v_0 - D_l \Delta_y v_0 = 0 & \text{in } B(x), \\
u_0(x, t) = v_0(x, y, t) & \text{at } (x, y) \in \Omega \times \partial B(x), \\
u_0(x, t) = u_0(x, t) & \text{at } x \in \partial \Omega, \\
u_0(x, 0) = u_l(x) & \text{in } \overline{\Omega}, \\
v_0(x, y, 0) = v_l(x, y) & \text{at } (x, y) \in \overline{\Omega} \times \overline{B(x)}. 
\end{cases}
\]

Before starting to discuss the existence and uniqueness of weak solutions to problem \((P)\), we denote \(U := u - u_b\) and notice that \(U = 0\) at \(\partial \Omega\).

**Definition 4.5** Assume (B1) and (B2). The pair \((u, v)\), with \(u = U + u_b\) where \((U, v) \in \mathbb{V}\), is a weak solution of the problem \((P)\) if the following identities hold
\[
\int_{\Omega} \theta \partial_t (U + u_b) \phi \, dx + \int_{\Omega} (D \nabla_x (U + u_b) - q (U + u_b)) \cdot \nabla_x \phi \, dx = - \int_{\partial B(x)} \nu_0 \cdot (D_l \nabla_y v_0) \phi \, d\sigma \, dx, 
\]
\[
\int_{\Omega} \int_{B(x)} \partial_t v \psi \, dy \, dx + \int_{\Omega} \int_{B(x)} D_l \nabla_y \cdot \nabla_y \psi \, dx = \int_{\partial B(x)} \nu_0 \cdot (D_l \nabla_y v_0) \phi \, d\sigma \, dx, 
\]
for all \((\phi, \psi) \in \mathbb{V}\) and \(t \in I\).
Proposition 4.6 (Uniqueness) Assume (B1) and (B2). Problem (P) admits at most one weak solution in the sense of Definition 4.5.

Proof Since Problem (P) is linear, the uniqueness follows in the standard way and can be done directly in the $x$-dependent function spaces: One takes two different weak solutions to (P) satisfying the same initial data. Testing with their difference and using the Gronwall’s inequality conclude the proof.

Theorem 4.7 Assume (B1) and (B2). Problem (P) admits at least a global-in-time weak solution in the sense of Definition 4.5.

Proof See the proof of Theorem 5.11 in [30].

To get the correctors estimates stated in Theorem 3.1 we need more two-scale regularity for the macroscopic reconstruction of the concentration field $v_0$. We state this fact in the following result:

Lemma 4.8 (Additional two-scale regularity) Assume (B1) and (B2). Then

$$v_0^\epsilon \in L^2(I; H^2(\Omega; H^2(B(x))))).$$ (4.17)

Proof The proof of this result is similar to the regularity lift proven in Claim 5.10 in [30]. The main ingredients are fixing of the boundary and testing with difference quotients in the weak formulation posed in fixed domains. We omit to show the details.

Theorem 4.9 (On strong solutions) Assume (B1), (B2), and (B3). Problem (P) admits one global-in-time strong solution.

Proof Under the assumptions (B1) and (B2), Theorem 4.7 guarantees the existence of global-in-time weak solutions. Relying on the assumption (B3), we can lift the regularity until getting a strong solution. A similar calculation is done in [16] (Theorem 5, pp. 360–364). In particular, (B3) allows for a regularity lift such that

$$\|\nabla \partial_t u_0\|_{L^2(I \times \Omega)} + \|\nabla \partial_t v_0\|_{L^2(I \times \Omega \times Y)} \leq c.$$

For our purpose, we only need

$$\|\nabla \partial_t u_0^\epsilon\|_{L^2(I \times \Omega_\epsilon)} \leq c,$$ (4.18)

$$\|v_0^\epsilon\|_{L^2(I, H^2(\Omega_\epsilon^\theta))} \leq c$$ (4.19)

where $u_0^\epsilon$ is the macroscopic reconstruction of $u_0$. Quite probably (4.19) could be relaxed to $\|u_0^\epsilon\|_{L^2(I, H^{2+\theta}(\Omega_\epsilon^\theta))}$ for some $\theta > 0$, but we don’t address here this issue. Since we rather wish that the reader focusses on our strategy of getting the correctors, we omit to show the proof details for this regularity result.
5 Proof of Theorem 3.1

In this section, we give the proof of the main result of our paper, i.e. of Theorem 3.1. The proof uses the auxiliary results stated in the lemmas below. They mainly concern integral estimates for rapidly oscillating functions with prescribed average; Related estimates can be found, for instance, in [7] and Section 1.5 in [10].

Lemma 5.1 Assume the hypothesis of Theorem 3.1 to hold. Then

\[
\int_{Y(x)} \left( \nabla_x \cdot ((I + \nabla y M) \nabla_x u_0) - \frac{1}{\theta(x)} \nabla_x \cdot \int_{Y(x)} (I + \nabla y M) \nabla_x u_0 \, dy \right) \, dy = -\int_{\partial B(x)} \nu_1 \cdot (I + \nabla y M) \nabla_x u_0 \, d\sigma.
\]

Proof We compute

\[
\int_{Y(x)} \left( \nabla_x \cdot ((I + \nabla y M) \nabla_x u_0) - \frac{1}{\theta(x)} \nabla_x \cdot \int_{Y(x)} (I + \nabla y M) \nabla_x u_0 \, dy \right) \, dy = \\
\int_{Y(x)} \nabla_x \cdot ((I + \nabla y M) \nabla_x u_0 \, dy - \nabla_x \cdot \int_{Y(x)} (I + \nabla y M) \nabla_x u_0 \, dy.
\]

Reynolds’s transport theorem (see for instance [20]) gives

\[
\nabla_x \cdot \int_{Y(x)} ((I + \nabla y M) \nabla_x u_0 \, dy = \int_{Y(x)} \nabla_x \cdot ((I + \nabla y M) \nabla_x u_0) \, dy \\
+ \int_{\partial B(x)} \frac{\nabla x S}{|\nabla y S|} (I + \nabla y M) \nabla_x u_0 \, d\sigma.
\]

By the boundary condition in (2.14), we have

\[
\nu_0 (I + \nabla y M) = \frac{\nabla y S}{|\nabla y S|} (I + \nabla y M) = 0 \text{ on } \partial B(x),
\]

so that we can write, using (2.5),

\[
\frac{\nabla x S}{|\nabla y S|} (I + \nabla y M) \nabla_x u_0 = \left( \frac{\nabla x S}{|\nabla y S|} - \frac{\nabla x S \cdot \nabla y S}{|\nabla y S|^2} \frac{\nabla y S}{|\nabla y S|} \right) (I + \nabla y M) \nabla_x u_0 \\
= \nu_1 \cdot (I + \nabla y M) \nabla_x u_0
\]

on \( \partial B(x) \). Combining the above expressions proves the conclusion of this lemma. \( \square \)

Lemma 5.2 Assume the hypothesis of Theorem 3.1 to hold. Let \( Q(x, y) \in L^2(\Omega; L^2(B(x))) \) and \( p \in L^2(\Omega; L^2(\partial B(x))) \). Furthermore, suppose that \( \int_{Y(x)} Q(x, y) \, dy = \int_{\partial B(x)} p(x, y) \, d\sigma \). Then the inequality

\[
\left| \int_{\Omega_{\epsilon}} Q(x, x/\epsilon) \phi(x) \, dx - \epsilon \int_{\Gamma_{\epsilon}} p(x, x/\epsilon) \phi(x) \, ds \right| \leq C \epsilon \| \phi \|_{H^1(\Omega_{\epsilon})}
\]

holds for every \( \phi \in H^1(\Omega_{\epsilon}; \partial \Omega) \). The constant \( C \) does not depend on the choice of \( \epsilon \).
Proof The problem
\[ \Delta_y \Psi(x, y) = Q(x, y) \text{ in } Y(x) \]
\[ \nu_0 \cdot \nabla_y \Psi = p(x, y) \text{ on } \partial B(x) \]
has a 1-periodic in \( y \) solution that is unique up to an additive constant. We multiply the first equation above with \( \phi \) and integrate over \( \Omega_h \) and use the thus obtained equality to get:
\[
\begin{align*}
\left| \int_{\Omega_h} Q(x, x/\epsilon) \phi(x) \, dx - \epsilon \int_{\Gamma^+} p(x, x/\epsilon) \phi(x) \, ds \right| &= \\
\left| \int_{\Omega_h} \Delta_y \Psi(x, y)\big|_{y=\frac{x}{\epsilon}} \phi(x) \, dx - \epsilon \int_{\Gamma^+} p(x, x/\epsilon) \phi(x) \, ds \right| &= \\
\epsilon \int_{\Omega_h} \left( \nabla_x \left[ \nabla_y \Psi(x, y)\big|_{y=\frac{x}{\epsilon}} \right] - \nabla_x \nabla_y \Psi(x, y)\big|_{y=\frac{x}{\epsilon}} \right) \phi(x) \, dx - \epsilon \int_{\Gamma^+} p(x, x/\epsilon) \phi(x) \, ds &= \\
\epsilon \int_{\Gamma^+} (\nu_0 + \epsilon \nabla \Psi(a, y))\big|_{y=\frac{x}{\epsilon}} \cdot \nabla_x \phi(x) \, dx - \epsilon \int_{\Omega_h} \nabla_y \Psi\big|_{y=\frac{x}{\epsilon}} \nabla_x \phi(x) \, dx &= \\
-\epsilon \int_{\Omega_h} \nabla_x \nabla_y \Psi(x, y)\big|_{y=\frac{x}{\epsilon}} \phi(x) \, dx - \epsilon \int_{\Gamma^+} p(x, x/\epsilon) \phi(x) \, ds \leq \\
\epsilon^2 \left| \int_{\Omega_h} \nabla_x \nabla_y \Psi(a, y)\big|_{y=\frac{x}{\epsilon}} \phi(x) \, dx \right| + \epsilon \left| \int_{\Omega_h} \nabla_y \Psi\big|_{y=\frac{x}{\epsilon}} \nabla_x \phi(x) \, dx \right| &= \\
+ \epsilon \left| \int_{\Omega_h} \nabla_x \nabla_y \Psi(x, y)\big|_{y=\frac{x}{\epsilon}} \phi(x) \, dx \right| &\leq \epsilon C \| \phi \|_{H^1(\Omega_h)}
\end{align*}
\]

The lemma is now proved. \(\square\)

The last auxiliary lemma is a special case of Lemma 4 in [7], and therefore we will state it here without proof.

Lemma 5.3 Let \( \Pi_\epsilon \) be a subset of \( \{ x \in \Omega | \operatorname{dist}(x, \partial \Omega) \leq \frac{\sqrt{2}}{2} \epsilon \} \). Then the following inequality
\[
\left| \int_{\Pi_\epsilon} \nabla_x u_0 \phi \, dx \right| \leq C \epsilon^{3/2} \| \phi \|_{H^1(\Omega_h)}
\]
holds for all \( \phi \in H^1(\Omega_h, \partial \Omega) \). The constant \( C \) does not depend on \( \epsilon \).

Proof (of Theorem 3.1) We define
\[
z_\epsilon(x, t) := u_0(x, t) + \epsilon \chi_\epsilon(x) M(x, x/\epsilon) \nabla u_0(x, t) - u_\epsilon(x, t),
\]
\[
w_\epsilon(x, t) := v_\epsilon(x, x/\epsilon, t) - v_\epsilon(x, t).
\]
By, e.g., Theorem 4 in [23], the functions \( M(x, x/\epsilon) \) and \( v_\epsilon(x, x/\epsilon, t) \) are well-defined functions in \( H^1(\Omega_h) \) and \( L^2(I; H^1(\Omega_h)) \), respectively, and furthermore, we know by con-
struction that there exists a $C > 0$ such that

$$
\| \tau_\epsilon \|_{L^2(I, H^1(\Omega_\epsilon)))} \leq C, \quad (5.1)
$$

$$
\| w_\epsilon \|_{L^2(I, H^1(\Omega_\epsilon)))} \leq \epsilon C, \quad (5.2)
$$

where the constant $C$ is independent of the choice of $\epsilon$. In the following we will use the notation $u_1(x, y, t) = M(x, y) \nabla u_0(x, t)$. We compute:

$$
\Delta z_\epsilon(x, t) = \Delta u_0(x, t) + \epsilon \chi_\epsilon \Delta_x u_1(x, y, t) + 2 \chi_\epsilon \nabla_x \cdot \nabla_y u_1(x, y, t) \mid_{y = \tilde{z}} + 2 \chi_\epsilon \nabla_x \cdot \nabla_y u_1(x, y, t) \mid_{y = \tilde{z}} - \Delta u_1(x, t)
$$

$$
\Delta w_\epsilon(x, \epsilon, t) = \Delta x v_0(x, t) + \epsilon^{-1} \nabla_x \cdot \nabla_y v_0(x, y, t) \mid_{y = \tilde{z}} + \epsilon^{-1} \nabla_y \cdot \nabla_x v_0(x, y, t) \mid_{y = \tilde{z}} + \frac{1}{\epsilon^2} \Delta y v_0(x, y, t) \mid_{y = \tilde{z}} - \Delta x v_1(x, y, t) \mid_{y = \tilde{z}}.
$$

We use that

$$
\theta(x) \partial_t u_0 - \nabla_x \cdot (D(x) \nabla_x u_0 - q u_0) = - \int_{\partial B(x)} \nu_0 \cdot (D_l \nabla_y v_0) \, d\sigma
$$

and $\Delta_y u_1(x, y) = 0$ and $\partial_t u_\epsilon = \nabla \cdot (D_h \nabla u_\epsilon - q \cdot u_\epsilon)$ to obtain

$$
D_h \Delta x z_\epsilon - \partial_t z_\epsilon = D_h \Delta x u_0 + \epsilon \chi_\epsilon D_h \Delta_x u_1 + 2 \chi_\epsilon D_h \nabla_x \cdot \nabla_y u_1 + \epsilon D_h \Delta \chi_\epsilon u_1
$$

$$
+ 2 \epsilon D_h \nabla \chi_\epsilon \cdot \nabla_x u_1 + 2 D_h \nabla \chi_\epsilon \cdot \nabla_y u_1
$$

$$
- \frac{1}{\bar{y}} \left( \nabla_x \cdot (D(x) \nabla_x u_0 - \bar{q} u_0) - \int_{\partial B(x)} \nu_0 \cdot (D_l \nabla_y v_0) \, d\sigma \right) - \epsilon \chi_\epsilon \partial_t u_1
$$

$$
- \nabla \cdot (q \cdot u_\epsilon),
$$

$$
\epsilon^2 D_l \Delta x w_\epsilon - \partial_t w_\epsilon = \epsilon^2 D_l \Delta x v_0 + \epsilon D_l (\nabla_x \cdot \nabla_y v_0 + \nabla_y \cdot \nabla_x v_0).
$$

On $\Gamma^v$ we have

$$
\nu^v \cdot \nabla z_\epsilon = - \nu^v \cdot \nabla u_\epsilon + \nu^v \cdot \nabla_x u_0 + \epsilon \nu^v \cdot \nabla_x u_1 + \nu^v \cdot \nabla_y u_1
$$

$$
= - \epsilon^2 \frac{D_l}{D_h} \nu^v \cdot \nabla u_\epsilon + \nu^v \cdot \nabla_x u_0 + \epsilon \nu^v \cdot \nabla_x u_1 + \nu^v \cdot \nabla_y u_1,
$$

$$
\nu^v \cdot \nabla w_\epsilon = - \nu^v \cdot \nabla u_\epsilon + \nu^v \cdot \nabla_x v_0 + \epsilon^{-1} \nu^v \cdot \nabla_y v_0.
Now, we multiply with $\phi$ and integrate by parts to get

$$
\int_{\Omega_h} \partial_t z_\epsilon \phi \, dx + \int_{\Omega_h} (D_h \nabla z_\epsilon \cdot \nabla \phi + q^e \cdot \nabla z_\epsilon \phi) \, dx = \epsilon \int_{\Omega_h} \chi_\epsilon \partial_t w_\epsilon \phi \, dx - \int_{\Omega_h} D_h \Delta_x u_0 \phi \, dx
$$

$$
- \epsilon \int_{\Omega_h} D_h \chi_\epsilon \Delta_x u_1 \phi \, dx - 2 \int_{\Omega_h} D_h \chi_\epsilon \nabla_x \cdot \nabla y \phi \, dx
$$

$$
+ \int_{\Omega_h} \frac{1}{\theta} (\nabla_x \cdot (D(x) \nabla x u_0) - \int_{\partial B(x)} \nu_0 \cdot (D_l \nabla y v_0) \, d\sigma) \phi \, dx
$$

$$
+ \epsilon^2 \int_{\Gamma^e} D_l \nu^e \cdot \nabla v_0 \phi \, ds - D_h \int_{\Gamma^e} \nu^e \cdot \nabla y u_0 \phi \, ds
$$

$$
- \epsilon D_h \int_{\Gamma^e} \nu^e \cdot \nabla x u_1 \phi \, ds - D_h \int_{\Gamma^e} \nu^e \cdot \nabla y u_1 \phi \, ds
$$

$$
- \int_{\Omega_h} (\epsilon D_h \Delta x u_1 + 2 \epsilon D_h \nabla \chi_\epsilon \cdot \nabla x u_1 + 2 D_h \nabla \chi_\epsilon \cdot \nabla y u_1) \phi \, dx
$$

$$
- \int_{\Omega_h} (\frac{1}{\theta} \bar{q} - q_\epsilon) \cdot \nabla u_0 \phi \, dx - \epsilon \int_{\Omega_h} \chi_\epsilon u_1 q_\epsilon \cdot \nabla \phi \, dx,
$$

which holds

$$
(\nabla_y \cdot \nabla x u_1(x,y))|_{y=x/\epsilon} = \epsilon \nabla_x \cdot (\nabla x u_1(x,x/\epsilon)) - \epsilon (\Delta x u_1(x,y))|_{y=x/\epsilon},
$$

We take into account the identity

$$
(\nabla_y \cdot \nabla x u_1(x,y))|_{y=x/\epsilon} = \epsilon \nabla_x \cdot (\nabla x u_1(x,x/\epsilon)) - \epsilon (\Delta x u_1(x,y))|_{y=x/\epsilon},
$$

which gives

$$
\epsilon D_h \int_{\Gamma^e} \nu^e \cdot \nabla x u_1|_{y=x/\epsilon} z_\epsilon \, ds = \epsilon D_h \int_{\Omega_h} \nabla x u_1|_{y=x/\epsilon} \cdot \nabla (\chi_\epsilon z_\epsilon) + \chi_\epsilon z_\epsilon \nabla \cdot (\nabla x u_1|_{y=x/\epsilon}) \, dx
$$

$$
= \epsilon D_h \int_{\Omega_h} \nabla x u_1 \cdot \nabla (\chi_\epsilon z_\epsilon) + \chi_\epsilon z_\epsilon \Delta_x u_1 \, dx
$$

$$
+ D_h \int_{\Omega_h} \chi_\epsilon z_\epsilon \nabla_y \cdot \nabla x u_1 \, dx,
$$

and also the boundary condition $\nu_0 \cdot \nabla y u_1 = -\nu_0 \cdot \nabla x u_0$ for $y \in \partial B(x)$, which holds also on $\Gamma^e$, we add the two equations (5.3) and (5.5), substitute $\phi = z_\epsilon$ and $\psi = w_\epsilon$ and
Corrector estimates of a locally-periodic scenario

\[
\frac{1}{2} \partial_t \| z^\epsilon \|_{L^2(\Omega^\epsilon)} + \frac{1}{2} \partial_t \| w^\epsilon \|_{L^2(\Omega^\epsilon)} + \int_{\Omega^\epsilon} (D_h \nabla z^\epsilon \cdot \nabla z^\epsilon + q^\epsilon \cdot \nabla z^\epsilon) \, dx + \epsilon^2 D_l \| \nabla w^\epsilon \|_{L^2(\Omega^\epsilon)}^2 =
\]

\[
- \int_{\Omega^\epsilon} D_h \nabla u_0 z^\epsilon \, dx - \int_{\Omega^\epsilon} \chi_e D_h (\nabla_x \cdot \nabla_y u_1) z^\epsilon \, dx + \int_{\Omega^\epsilon} \frac{1}{\theta} \nabla_x \cdot (D(x) \nabla_x u_0) z^\epsilon \, dx
\]

\[
- \epsilon D_h \int_{\Gamma^*} \nu^\epsilon \cdot (\nabla_x u_0 + \nabla_y u_1) z^\epsilon \, ds
\]

\[
- \int_{\Omega^\epsilon} \left( \int_{\partial B(x)} \nu^\epsilon_0 \cdot (D_l \nabla_y v_0) \, d\sigma \right) z^\epsilon \, dx + \epsilon \int_{\Gamma^*} D_l \nu^\epsilon \cdot \nabla_y v_0 z^\epsilon \, ds
\]

\[
+ \epsilon \int_{\Omega^\epsilon} \chi_e \partial_t u_1 z^\epsilon \, dx - \epsilon \int_{\Omega^\epsilon} D_h \nabla u_1 \cdot \nabla (\chi_e z^\epsilon) \, dx
\]

\[
- \epsilon^2 \int_{\Omega^\epsilon} D_l \nabla v_0 w^\epsilon \, dx - \epsilon \int_{\Omega^\epsilon} D_l (\nabla_x \cdot \nabla_y v_0 + \nabla_y \cdot \nabla_x v_0) w^\epsilon \, dx + \epsilon^2 \int_{\Gamma^*} D_l \nu^\epsilon \cdot \nabla_x v_0 w^\epsilon \, ds
\]

\[
+ \epsilon^2 \int_{\Gamma^*} D_l \nu^\epsilon \cdot (\nabla v_0 - \nabla_y u_0) u_1 \, ds - \int_{\Omega^\epsilon} \left( \epsilon D_h \nabla \chi_e u_1 + 2 \epsilon D_h \nabla \chi_e \cdot \nabla x u_1 + 2 D_h \nabla \chi_e \cdot \nabla y u_1 \right) z^\epsilon \, dx
\]

\[
- \int_{\Omega^\epsilon} \left( \frac{1}{\theta} y - q^\epsilon \right) \cdot \nabla u_0 z^\epsilon \, dx - \epsilon \int_{\Omega^\epsilon} \chi_e u_1 q^\epsilon \cdot \nabla z^\epsilon \, dx,
\]

where we have also used that \( \phi - \psi = z^\epsilon - w^\epsilon = \epsilon u_1 \) on \( \Gamma^* \) and \( \phi = \epsilon u_1 \) on \( \partial \Omega \).

We know that there exist \( \beta > 0 \) and \( \gamma \geq 0 \) such that

\[
\beta \| z^\epsilon \|_{H^1(\Omega^\epsilon)} \leq \int_{\Omega^\epsilon} (D_h \nabla z^\epsilon \cdot \nabla z^\epsilon + q^\epsilon \cdot \nabla z^\epsilon) \, dx + \gamma \| z^\epsilon \|_{L^2(\Omega^\epsilon)}.
\]

and we use this to estimate

\[
\frac{1}{2} \partial_t \| z^\epsilon \|_{L^2(\Omega^\epsilon)} + \frac{1}{2} \partial_t \| w^\epsilon \|_{L^2(\Omega^\epsilon)} + \beta \| z^\epsilon \|_{H^1(\Omega^\epsilon)}^2 + \epsilon^2 D_l \| \nabla w^\epsilon \|_{L^2(\Omega^\epsilon)}^2 \leq \gamma \| z^\epsilon \|_{L^2(\Omega^\epsilon)} + I_1 + I_2 + \ldots + I_{11}
\]
where

\[ I_1 = \int_{\Omega_h} D_h \nabla_x \cdot (\nabla_x u_0 + \nabla_y u_1) z_\epsilon \, dx - \int_{\Omega_h} \frac{1}{\theta} \nabla_x \cdot (D(x) \nabla_x u_0) z_\epsilon \, dx \]

\[ + \epsilon D_h \int_{\Gamma^\epsilon} \nu_1 \cdot (\nabla_x u_0 + \nabla_y u_1) z_\epsilon \, ds \],

\[ I_2 = \int_{\Omega_h} (\int_{\partial B(x)} \nu_0 \cdot (D_l \nabla_y v_0) \, d\sigma) z_\epsilon \, dx - \epsilon \int_{\Gamma^\epsilon} D_l \nu_0 \cdot \nabla_y v_0 z_\epsilon \, ds \],

\[ I_3 = \int_{\Omega_h} (1 - \chi_\epsilon) D_h (\nabla_x \cdot \nabla_y u_1) z_\epsilon \, dx \],

\[ I_4 = \epsilon^2 \int_{\Gamma^\epsilon} \left( D_h (\nu_2 + O(\epsilon)) \cdot (\nabla_x u_0 - \nabla_y u_1) + D_l \nu_\epsilon^\theta \cdot \nabla_y v_0 \right) z_\epsilon \, ds \],

\[ I_5 = \int_{\Omega_h} (\epsilon D_h \Delta \chi_\epsilon u_1 + 2\epsilon D_h \nabla \chi_\epsilon \cdot \nabla_x u_1 + 2D_h \nabla \chi_\epsilon \cdot \nabla_y u_1) z_\epsilon \, dx \],

\[ I_6 = \epsilon \int_{\Omega_h} \chi_\epsilon \partial_\nu u_1 z_\epsilon \, dx \],

\[ I_7 = \epsilon \int_{\Omega_h} D_h \nabla_x u_1 \cdot \nabla (\chi_\epsilon z_\epsilon) \, dx \],

\[ I_8 = \epsilon^2 \int_{\Omega_h} D_l \Delta_x v_0 \, dx + \epsilon \int_{\Omega_h} D_l (\nabla_x \cdot \nabla_y v_0 + \nabla_y \cdot \nabla_x v_0) w_\epsilon \, dx - \epsilon^2 \int_{\Gamma^\epsilon} D_l \nu_\epsilon \cdot \nabla_x v_0 w_\epsilon \, ds \],

\[ I_9 = \epsilon^2 \int_{\Gamma^\epsilon} D_l \nu_\epsilon \cdot (\epsilon \nabla v_\epsilon - \nabla y v_0) u_1 \, ds \],

\[ I_{10} = \int_{\Omega_h} \frac{1}{\theta} (\bar{q} - q_\epsilon) \cdot \nabla u_0 z_\epsilon \, dx \],

\[ I_{11} = \epsilon \int_{\Omega_h} \chi_\epsilon u_1 q_\epsilon \cdot \nabla z_\epsilon \, dx \].

For \( I_1 \) we use that \( u_1 = M \nabla u_0 \) and that \( D(x) := D_h \int_{Y(x)} (I + \nabla_y M) \, dy \). We set

\[ Q(x, y) = \nabla_x \cdot ((I + \nabla_y M) \nabla_x u_0) - \frac{1}{\theta(x)} \nabla_x \cdot \int_{Y(x)} (I + \nabla_y M) \nabla_x u_0 \, dy, \]

\[ p(x, y) = -\nu_1 \cdot (I + \nabla_y M), \]

and use Lemma 5.2 to obtain \( I_1 \leq \epsilon C \| z_\epsilon \|_{H^1(\Omega_h)} \). Lemma 5.1 asserts that the conditions of Lemma 5.2 are satisfied for these choices of \( Q \) and \( p \).

For \( I_2 \) we also apply Lemma 5.2, this time for the choice

\[ Q(x, y) = \frac{1}{\theta(x)} \int_{\partial B(x)} \nu_0 \cdot \nabla y v_0 \, d\sigma, \]

\[ p(x, y) = \nu_0 \cdot \nabla y v_0, \]
Corrector estimates of a locally-periodic scenario

and thus to Using the energy bounds (5.1) and (5.2) together with a Gronwall-type argument lead to

which, in particular, implies

and thus

Combining this with (5.6) gives the result

where the constant $c$ is independent of $\epsilon$. The last step uses the evident estimate $\|\epsilon v_1 (1 - \chi_\epsilon)\|_{H^1(\Omega^\epsilon)} \leq C\sqrt{\epsilon}$, and the theorem is proven.

Acknowledgments

We acknowledge fruitful discussions with Gregory Chechkin regarding homogenization techniques for non-periodic media. We also thank Eduard Marusic-Paloka for an interesting correspondence on the best corrector estimates (upper bounds on convergence rates) existing for the stationary Stokes and Navier-Stokes problems.
