Publisher's PDF, also known as Version of Record (includes final page, issue and volume numbers)

Please check the document version of this publication:
• A submitted manuscript is the author's version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.
• The final author version and the galley proof are versions of the publication after peer review.
• The final published version features the final layout of the paper including the volume, issue and page numbers.

Sustainable Construction
Strategic approach to construction material management for waste reduction

Subject
The Construction sector takes up to 50% of all materials extracted from the earth’s crust and in combination with energy produces goods and huge amounts of waste (reported up to 44% of the waste stream arriving at landfills). And the question is why so much material is lost as waste?

Goal
It is to investigate the construction sector in a developing country (Costa Rica) focusing on construction materials (mainly concrete, steel and wood) and processes.

This research looks into the flows of materials going into the construction process, the ways how they are “metabolized” (consumed) and the major factors (causes) that influence the production of solid waste.

Expected Results
The expected results fall into theoretical developments of Industrial Metabolism, a documented example of the use of the Material Flow Analysis (MFA) approach for construction materials and an improved MFA for the construction sector.

Material consumption (virgin materials) → Construction Industry → Waste generation

Construction waste dumped in the ocean
Construction waste dumped on a river side

Subject
The construction sector plays a key role in shaping and developing the built environment. It also has an undisputed and significant impact on it due to the amounts of materials extracted and produced as waste.
The construction industry has emphasized to recycling construction waste (CW), however, relatively less emphasis has been paid on construction waste minimization. CW reduction can be achieved through changes in design concepts, material and construction methods selection and material management and very few studies are found in the literature related to these topics.

Goals
The motivation for this research is to examine the physical processes that convert raw materials, plus labour, into finished products and wastes.

Research Question
To which extend industrialised construction contribute to the reduction of CW in Costa Rica?

Strategy
The strategy is to use industrial metabolism theories in order to model the construction system and the mutual interchange of physical flows between its subsystems, and the interchange of physical flows between the industrial system and its natural environment”.

Expected Results
One of the results is to develop and test a strategy for material flow analysis (MFA) for the construction industry, a second result is to develop a documented example of the practical use of MFA approach and to enrich the studies on material management practices in the sector.
