Document Version:
Publisher’s PDF, also known as Version of Record (includes final page, issue and volume numbers)

Please check the document version of this publication:
• A submitted manuscript is the version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.
• The final author version and the galley proof are versions of the publication after peer review.
• The final published version features the final layout of the paper including the volume, issue and page numbers.

Introduction

The performance and operating range of centrifugal compressors is limited by the occurrence of an aerodynamic instability called surge. This instability can lead to severe damage of the machine due to large mechanical and thermal loads. A way to cope with this instability is active control. In this approach, perturbations are fed back into the flow field in order to modify the dynamics of the compression system. Such techniques can extend the stable operating range towards lower mass flows, which makes the compressor more versatile. See also Figure 1. Furthermore it enables the safe operation of the compressor near the surge point.

Compression system model

The suggested approach is applied to an experimental compression system with a rated power of 250 kW. To describe the dynamic behaviour of the examined compression system, the model suggested in [1] is used. The lumped parameter model is schematically shown in Figure 2. By introducing a dimensionless mass flow \( \phi \), pressure rise \( \psi \), and time scale \( \tilde{t} \), the following set of equations is obtained

\[
\begin{align*}
\frac{d\phi}{dt} &= B(\psi_c - \psi) \\
\frac{d\psi}{dt} &= \frac{F}{B}(\phi_c - \phi_l - \phi_s)
\end{align*}
\]

where \( \psi_c \) represents the nonlinear steady-state compressor pressure rise shown in Figure 1. The parameters \( \phi_l \) and \( \phi_s \) represent relations for the throttle mass flows.

Model validation

In order to validate the obtained model, simulation results are compared with experimental surge measurements. Figure 3 shows that both the amplitude and frequency of the surge oscillations are captured well by the model. Furthermore, a sensitivity analysis is carried out. This analysis provides measures for the relative importance of the various model parameters. The results also form the starting point for the analysis of the linearized model and the design of a stabilizing feedback controller.
