Model reduction of port-Hamiltonian systems
based on reduction of Dirac structures

February 2, 2011

Rostyslav V. Polyuga\textsuperscript{1}, Arjan van der Schaft\textsuperscript{2}

Abstract

The geometric formulation of general port-Hamiltonian systems is used in order to obtain two structure preserving reduction methods. The main idea is to construct a reduced-order Dirac structure corresponding to zero power flow in some of the energy-storage ports. This can be performed in two canonical ways, called the effort- and the flow-constraint methods. We show how the effort-constraint method can be regarded as a projection-based model reduction method.

Keywords: port-Hamiltonian systems; structure preserving model reduction; Dirac structure; effort-constraint method; flow-constraint method.

1 Introduction

A standard way to model large-scale physical systems is network modeling. In this approach the overall system is decomposed into (possibly many) interconnected subsystems. Network modeling has many advantages, such as reusability of subsystem models (libraries), flexibility (coarse models of subsystems may be replaced by more refined ones, leaving the rest of the system modeling untouched), hierarchical modeling, and control (by adding new subsystems as control components). In port-based network modeling (e.g., bond graph modeling) the overall system is decomposed into subsystems which are interconnected to each other through (vector) pairs of variables, whose product is the power exchanged among the subsystems. This approach is especially useful for the systematic modeling of multi-physics systems, where the subsystems belong to different physical domains (mechanical, electrical, hydraulic, etc.).

Since the beginning of the nineties of the previous century it has been realized \cite{22, 5, 21, 20, 11} that the mathematical models arising from port-based network modeling have an insightful geometric structure, which can be regarded as a generalization of the geometric formulation of analytical mechanics into its Hamiltonian form. These geometric dynamical system models that follow directly from port-based network modeling have been called port-Hamiltonian systems \cite{22, 21, 3}.

The state-space dimensions of mathematical models arising from network modeling easily become very large; think e.g. of electrical circuits, multi-body systems, or spatial discretization of distributed-parameter systems. Thus there is an immediate need for model reduction methods. However, since we want the reduced order models again to be interconnectable to other (sub-)systems, we want to retain the port-Hamiltonian structure of the reduced order systems. Furthermore, we want to preserve structural properties, such as energy conservation, passivity and existence of conservation laws as implied by the port-Hamiltonian structure. Thus the problem arises of structure preserving model reduction of port-Hamiltonian systems.

The geometric formulation of port-Hamiltonian systems motivates a model reduction approach for general port-Hamiltonian systems (possibly also including the algebraic constraints), which involves the construction of a reduced order Dirac structure, and subsequently the construction of a reduced Hamiltonian. This approach is directly based on port-based modeling by replacing interconnections with almost zero energy flow by zero-power constraints. In this paper we treat two canonical structure preserving model reduction methods, called the effort-constraint reduction method and the flow-constraint reduction method. We show how the effort-constraint method in suitable coordinates can be regarded as a projection-based model reduction method. We suggest these coordinates for the effort-constraint method and balanced coordinates for both the effort- and flow-constraint methods as a possible choice of the coordinate system in order to obtain the reduced order models.

Structure preserving model reduction of port-Hamiltonian systems was also studied in \cite{13, 12, 18}. The perturbation approach is considered in \cite{10, 9}. The use of the Krylov methods is addressed in \cite{16, 8, 17, 24}, see also \cite{14}. Recent overview of port-Hamiltonian model reduction methods can be found in \cite{15}. For a general overview of model reduction techniques we refer the reader to \cite{1, 19}.

Preliminary results of this work are presented in \cite{23}.

The paper is organized as follows. The general definition of port-Hamiltonian systems using the notion of Dirac structure is given in Section 2. In Section 3 we explain the idea behind structure preserving model reduction based on zero-power constraints. Equational representations of the reduced order models are given in Section 4. These equational representations give rise to the effort- and flow-constraint reduced models for linear input-state-output port-Hamiltonian systems in Section 5. A numerical example, presented in Section 6, illustrates the performance of the effort- and flow-constraint reduction methods.
Figure 1: Geometric definition of a port-Hamiltonian system

2 Dirac structures and Port-Hamiltonian systems

The first main ingredient in the definition of a port-Hamiltonian system is the notion of a Dirac structure, which relates the power variables of the composing elements of the system in a power-conserving manner. The power variables always appear in conjugated pairs (such as voltages and currents, or generalized forces and velocities), and therefore mathematically they are modeled to take their values in dual linear spaces.

**Definition 1** [4] Let $\mathcal{F}$ be a linear space with a dual space $\mathcal{E} := \mathcal{F}^*$, and a duality product denoted as $\langle e \mid f \rangle \in \mathbb{R}$, with $f \in \mathcal{F}$ and $e \in \mathcal{E}$. In vector notation we simply write the duality product as $\langle e \mid f \rangle = e^T f$. We call $\mathcal{F}$ the space of flow variables, and $\mathcal{E} = \mathcal{F}^*$ the space of effort variables. Define on $\mathcal{F} \times \mathcal{E}$ the following indefinite bilinear form

$$\langle (f_1, e_1), (f_2, e_2) \rangle = \langle e_1 \mid f_2 \rangle + \langle e_2 \mid f_1 \rangle,$$

A subspace $\mathcal{D} \subset \mathcal{F} \times \mathcal{E}$ is a constant Dirac structure if $\mathcal{D} = \mathcal{D}^\perp$, where $\mathcal{D}^\perp$ is the orthogonal complement of $\mathcal{D}$ with respect to the indefinite bilinear form $\langle \cdot, \cdot \rangle$.

**Remark 1** It can be shown [4, 5, 3] that in the case of a finite-dimensional linear space $\mathcal{F}$, a Dirac structure $\mathcal{D}$ is equivalently characterized as a subspace such that $e^T f = \langle e \mid f \rangle = 0$ for all $(f, e) \in \mathcal{D}$, together with $\dim \mathcal{D} = \dim \mathcal{F}$. The property $\langle e \mid f \rangle = 0$ for all $(f, e) \in \mathcal{D}$ corresponds to power conservation.

A *port-Hamiltonian system* is defined as follows. We start with a Dirac structure $\mathcal{D}$ (see Fig. 1) on the space of all flow and effort variables involved:

$$\mathcal{D} \subset \mathcal{F}_x \times \mathcal{E}_x \times \mathcal{F}_R \times \mathcal{E}_R \times \mathcal{F}_P \times \mathcal{E}_P. \quad (1)$$

The space $\mathcal{F}_x \times \mathcal{E}_x$ is the space of flow and effort variables corresponding to the energy-storing elements (to be defined later on), the space $\mathcal{F}_R \times \mathcal{E}_R$ denotes the space of flow and effort variables of the resistive elements, while $\mathcal{F}_P \times \mathcal{E}_P$

---

3For the general definition of Dirac structures on manifolds we refer to e.g. [4, 5].
is the space of flow and effort variables corresponding to the external ports (or sources). The property $<e|f> = 0$ for all $(f,e) \in D$ implies that the power supplied through the external port is distributed between the energy-storing port and the resistive port.

The vector of all the flow and effort variables of a port-Hamiltonian system

$$f_x \in F_x, e_x \in E_x, f_R \in F_R, e_R \in E_R, f_P \in F_P, e_P \in E_P.$$  

is required to be in the Dirac structure

$$(f_x, e_x, f_R, e_R, f_P, e_P) \in D,$$  

(2)

The constitutive relations for the energy-storing elements are defined as follows. Let the Hamiltonian $H : X \rightarrow \mathbb{R}$ denote the total energy of the energy-storing elements with state variables $x = (x_1, x_2, \cdots, x_n)^T$; i.e., the total energy is given as $H(x)$. In the sequel we will take $X = F_x$ Then the energy-storage constitutive relations are given as

$$\dot{x} = -f_x, \quad e_x = \partial H / \partial x(x).$$  

(3)

This immediately implies the following energy balance

$$\frac{d}{dt} H = -e_x^T f_x,$$  

(4)

that is, the increase in total energy $H(x)$ is equal to the power $-e_x^T f_x$ provided to the energy-storing elements.

The constitutive relations for the resistive elements are given as

$$f_R = -\varphi(e_R),$$  

(5)

for some function $\varphi$ satisfying

$$e_R^T \varphi(e_R) > 0 \quad \text{for all} \quad e_R \neq 0.$$  

(6)

Linear resistive elements are given as

$$f_R = -R e_R, \quad R = R^T \succeq 0.$$  

(7)

The interpretation is that power is always dissipated by the resistive elements.

**Definition 2** Consider a Dirac structure (1), a Hamiltonian $H : X \rightarrow \mathbb{R}$ with constitutive relations (3), and a resistive relation $f_R = -\varphi(e_R)$ as in (5). Then the dynamics (2) of the resulting port-Hamiltonian system is given as

$$(-\dot{x}(t), \partial H / \partial x(x(t)), -\varphi(e_R(t)), e_R(t), f_P(t), e_P(t)) \in D.$$  

(8)
It follows \([21, 3]\) from the power-conservation property of Dirac structures, and (4) and (6) that
\[
\frac{d}{dt} H = -e_R^T e_R + e_P^T f_P \leq e_P^T f_P,
\]
thus showing passivity if the Hamiltonian \(H\) is bounded from below.

3 Structure preserving model reduction based on power conservation

Consider a general port-Hamiltonian system (8), with state variables \(x\) and total stored energy \(H(x)\). Let us assume that we have been able to find (e.g. by some balancing technique) a splitting of the state-space variables \(x = (x_1^T, x_2^T)^T\), \(x_1 \in \mathbb{R}^r\), \(x_2 \in \mathbb{R}^{n-r}\), having the property that the \(x_2\) coordinates hardly contribute to the input-output behavior of the system, and thus could be omitted from the state-space description. It is easily seen that the usual truncation method for obtaining a reduced order model in the reduced state \(x_1\) in general does not preserve the port-Hamiltonian structure, like it does also not preserve the passivity property, see e.g. [1], [15] (Remark 2.12). The same holds for the so-called singular perturbation reduction method, as was mentioned in [15] (Remark 2.14); see also [6], [7].

In which way is it possible to retain the port-Hamiltonian structure in model reduction? Recall that in the definition of a port-Hamiltonian system the vector of flow and effort variables (2) is required to be in the Dirac structure
\[
(f_1^x, f_2^x, e_1^x, e_2^x, f_R, e_R, f_P, e_P) \in \mathcal{D},
\]
while the flow and effort variables \(f_x, e_x\) are linked to the constitutive relations of the energy-storage by
\[
\dot{x}_1 = -f_1^x, \quad \frac{\partial H}{\partial x_1}(x_1, x_2) = e_1^x,
\]
\[
\dot{x}_2 = -f_2^x, \quad \frac{\partial H}{\partial x_2}(x_1, x_2) = e_2^x,
\]
which is shown in Fig. 2. This figure is a zoomed-in version of Fig. 1. The basic idea of structure preserving model reduction considered in this paper is to "cut" the interconnection
\[
\dot{x}_2 = -f_2, \quad \frac{\partial H}{\partial x_2}(x_1, x_2) = e_2,
\]
between the energy storage corresponding to \(x_2\) and the Dirac structure, in such a way that no energy is transferred. Hence the exchange of energy between the energy storage and the other system elements through the Dirac structure happens only via the port associated to \(x_1\), with \(x_1\) being the reduced order state vector.

The energy flow through the interconnection (11) is set equal to zero by making both power products
\[
(\frac{\partial H}{\partial x_2})^T \dot{x}_2 \quad \text{and} \quad (e_2)^T f_2
\]
equal to zero.

This can be done in the two following canonical ways (see also [23])

(i): Set

\[ \partial H \partial x_2(x_1, x_2) = 0, \quad e_2 = 0. \] (12)

The first equation imposes an algebraic constraint on the space variables \( x = (x_1^T, x_2^T)^T \). Under the general conditions on the Hamiltonian \( H \), this constraint allows one to solve for \( x_2 \) as a function of \( x_1 \): \( x_2 = x_2(x_1) \), leading to a reduced Hamiltonian

\[ H_{\text{red}}^\text{ec}(x_1) := H(x_1, x_2(x_1)). \]

Furthermore, the second equation defines the reduced Dirac structure\(^7\)

\[ \mathcal{D}_{\text{red}}^\text{ec} := \{(f_1^1, e_1^1, f_R, e_R, f_P, e_P) \mid \exists f_2 \text{ such that } (f_1^1, e_1^1, f_2, 0, f_R, e_R, f_P, e_P) \in \mathcal{D}\}, \]

leading to the reduced port-Hamiltonian system

\[ (-\dot{x}_1, \partial H_{\text{red}}^\text{ec} \partial x_1(x_1), -\varphi(e_R), e_R, f_P, e_P) \in \mathcal{D}_{\text{red}}^\text{ec}. \]

We will call this reduction method the effort-constraint reduction method, since it constrains the efforts \( e_2 \) and \( \partial H \partial x_2 \) to zero.

\(^7\mathcal{D}_{\text{red}}^\text{ec} \) is the composition of the full order Dirac structure \( \mathcal{D} \) with the Dirac structure on the space of flow and effort variables \( f_2, e_2 \) defined by \( e_2 = 0 \). It is proven in [2] that \( \mathcal{D}_{\text{red}}^\text{ec} \) is indeed a Dirac structure.
(ii): Set
\[ \dot{x}_2 = 0, \quad f_2 = 0. \] (13)

The first equation imposes the constraint
\[ x_2 = c, \]
where the constant \( c \) can be taken to be zero, and thus defines the reduced Hamiltonian
\[ H_{\text{red}}^c(x_1) := H(x_1, c), \] (14)
while the second equation leads to the reduced Dirac structure
\[ \mathcal{D}_{\text{red}}^c := \{(f_1^1, e_1^1, f_R, e_R, f_P, e_P) \mid \exists e_2 \text{ such that } \}
\[ (f_1^1, e_1^1, 0, f_R, e_R, f_P, e_P) \in \mathcal{D} \}, \] (15)
and the corresponding reduced port-Hamiltonian system
\[ (-\dot{x}_1, \frac{\partial H_{\text{red}}^c}{\partial x_1}(x_1), -\varphi(e_R), e_R, f_P, e_P) \in \mathcal{D}_{\text{red}}^c. \] (16)

We call this approach the flow-constraint reduction method, because it constrains the flows \(-\dot{x}_2, f_2\).

An important open question, which will not be answered in this paper, is how to choose the coordinates \([x_1 \ x_2]\) in such a way that the energy flow between the energy storage corresponding to \(x_2\) and the rest of the system through the Dirac structure is very small (negligible) at all time instants. Then the approximations (12) and (13) are at least from an energy transfer point of view well justified.

In Section 5.5 we will briefly discuss the closely related question of how to choose the coordinates in such a manner that the reduced model is close to the full order model from an input-output point of view.

4 Equational representations of the reduced order models

We will now provide explicit equational representations of the above two methods for structure preserving model reduction starting from the general representation by DAEs of the full order model (for details see [22, 5, 21, 3, 15]):
\[ F_x \dot{x} = E_x \frac{\partial H}{\partial x}(x) - F_R \varphi(e_R) + E_R e_R + F_P f_P + E_P e_P, \] (17)
where the matrices \( F_x, E_x, F_R, E_R, F_P, E_P \) satisfy [21, 3]
\[ E_x F_x^T + F_x E_x^T + E_R F_R^T + F_R E_R^T + E_P F_P^T + F_P E_P^T = 0, \]
\[ \text{rank} \begin{bmatrix} F_x & F_R & F_P & E_x & E_R & E_P \end{bmatrix} = n_x + n_R + n_p, \] (18)

7
with \( n_x = \dim \mathcal{F}_x \), \( n_R = \dim \mathcal{F}_R \), \( n_P = \dim \mathcal{F}_P \).

Corresponding to the splitting of the state vector \( x \) into \( x = (x_1^T, x_2^T)^T \), \( x_1 \in \mathbb{R}^r \), \( x_2 \in \mathbb{R}^{n-r} \), where \( r \) is the dimension chosen for the reduced order model, and the respective splitting of the flow and effort vectors \( f_x, e_x \) into \( f_1^x, f_2^x \) and \( e_1^x, e_2^x \), we write

\[
F_x = \begin{bmatrix} F_1^x & F_2^x \end{bmatrix}, \quad E_x = \begin{bmatrix} E_1^x & E_2^x \end{bmatrix}.
\]

(19)

Now the reduced Dirac structure \( \mathcal{D}_{\text{red}}^{\text{ec}} \) corresponding to the effort-constraint \( e_2^x = 0 \) is given by the explicit equations (see [2])

\[
L_{\text{ec}}^{\text{F}}_1 f_1^x + L_{\text{ec}}^{\text{E}}_1 e_1^x + L_{\text{ec}}^{\text{F}}_R f_R + L_{\text{ec}}^{\text{E}}_R e_R + L_{\text{ec}}^{\text{F}}_P f_P + L_{\text{ec}}^{\text{E}}_P e_P = 0,
\]

(20)

where \( L_{\text{ec}}^{\text{F}} \) is any matrix of maximal rank satisfying

\[
L_{\text{ec}}^{\text{F}}_2 F_2^x = 0.
\]

(21)

Similarly, the reduced Dirac structure \( \mathcal{D}_{\text{red}}^{\text{fc}} \) corresponding to the flow-constraint \( f_2^x = 0 \) is given by the equations

\[
L_{\text{fc}}^{\text{F}}_1 f_1^x + L_{\text{fc}}^{\text{E}}_1 e_1^x + L_{\text{fc}}^{\text{F}}_R f_R + L_{\text{fc}}^{\text{E}}_R e_R + L_{\text{fc}}^{\text{F}}_P f_P + L_{\text{fc}}^{\text{E}}_P e_P = 0,
\]

(22)

where \( L_{\text{fc}}^{\text{F}} \) is any matrix of maximal rank satisfying

\[
L_{\text{fc}}^{\text{F}}_2 E_2^x = 0.
\]

(23)

It follows that the reduced order model resulting from applying the effort-constraint method is given by

\[
L_{\text{ec}}^{\text{F}}_1 \dot{x}_1 = L_{\text{ec}}^{\text{F}}_1 \frac{\partial H_{\text{ec}}}{\partial x_1}(x_1) - L_{\text{ec}}^{\text{F}}_R \varphi(e_R) + L_{\text{ec}}^{\text{E}}_R e_R + L_{\text{ec}}^{\text{F}}_P f_P + L_{\text{ec}}^{\text{E}}_P e_P,
\]

(24)

whereas the reduced order model resulting from applying the flow-constraint method is given by

\[
L_{\text{fc}}^{\text{F}}_1 \dot{x}_1 = L_{\text{fc}}^{\text{F}}_1 \frac{\partial H_{\text{fc}}}{\partial x_1}(x_1) - L_{\text{fc}}^{\text{F}}_R \varphi(e_R) + L_{\text{fc}}^{\text{E}}_R e_R + L_{\text{fc}}^{\text{F}}_P f_P + L_{\text{fc}}^{\text{E}}_P e_P.
\]

(25)

The steps of model reduction leading to the reduced order models (24), (25) are depicted in Fig. 3. Firstly, we consider a full order port-Hamiltonian system with the corresponding full order Dirac structure. Secondly, we reduce the full order Dirac structure to obtain the reduced order Dirac structure. At the same time we are approximating the full order Hamiltonian of the full order model in order to obtain the reduced order Hamiltonian of the reduced order model. Note that the reduced order models obtained in this way are port-Hamiltonian by construction.
Figure 3: Steps of model reduction of a full order port-Hamiltonian system (PHS) with the Hamiltonian $H$ and the Dirac structure $\mathcal{D}$

5 Reduced models for linear input-state-output port-Hamiltonian systems

In this section we specialize the results of the previous section to the case of linear input-state-output port-Hamiltonian systems ([21, 3])

$$
\begin{align*}
\dot{x} &= (J - R)Qx + Gu, \quad J = -J^T, \quad R = R^T \succeq 0, \quad Q = Q^T, \\
y &= G^TQx.
\end{align*}
$$

(26)

The model (26) is obtained after the termination of the resistive port. In order to use the Dirac structure representation of this model (17) we rewrite (26) in the form

$$
\begin{align*}
\dot{x} &= JQx + G_Rf_R + Gu, \\
y &= G^TQx, \\
e_R &= G_R^TQx, \quad f_R = -\tilde{R}e_R,
\end{align*}
$$

(27)

where the matrix $\tilde{R}$ is such that

$$
G_RR_G^T = R.
$$

(28)

Splitting of the state vector into $x = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}, x_1 \in \mathbb{R}^r, x_2 \in \mathbb{R}^{n-r}$, for $r$ being the dimension of the reduced order model, then leads to the following partitioned
system description

\[
\begin{align*}
\begin{bmatrix}
\dot{x}_1 \\
\dot{x}_2
\end{bmatrix} &= \begin{bmatrix}
J_{11} & J_{12} \\
J_{21} & J_{22}
\end{bmatrix} \begin{bmatrix}
Q_{11} & Q_{12} \\
Q_{21} & Q_{22}
\end{bmatrix} \begin{bmatrix}
x_1 \\
x_2
\end{bmatrix} + \begin{bmatrix}
G_{R_1} \\
G_{R_2}
\end{bmatrix} f_R + \begin{bmatrix}
G_1 \\
G_2
\end{bmatrix} u, \\
y &= \begin{bmatrix}
G^T_1 & G^T_2
\end{bmatrix} \begin{bmatrix}
Q_{11} & Q_{12} \\
Q_{21} & Q_{22}
\end{bmatrix} \begin{bmatrix}
x_1 \\
x_2
\end{bmatrix}, \\
e_{R} &= \begin{bmatrix}
G^T_{R_1} & G^T_{R_2}
\end{bmatrix} \begin{bmatrix}
Q_{11} & Q_{12} \\
Q_{21} & Q_{22}
\end{bmatrix} f_R, \quad f_R = -\bar{R} e_{R}.
\end{align*}
\]

(29)

5.1 Effort-constraint method

Rewriting these equations into the form (17), and applying the general effort-constraint reduction method (20) from the previous section, yields (assuming that $Q_{22}$ is invertible) the reduced model

\[
\begin{align*}
\dot{x}_1 &= (J_{11} - R_{11})(Q_{11} - Q_{12}^{-1}Q_{22}^{-1}Q_{21})x_1 + G_1 u, \\
y_{ec} &= G^T_1(Q_{11} - Q_{12}^{-1}Q_{22}^{-1}Q_{21})x_1,
\end{align*}
\]

(30)

for the full order model (26). This reduced model was already obtained by direct methods in [12], as well as in scattering coordinates in [18].

Full details for the derivation of the reduced order model (30) are relegated to Appendix A.

5.2 Flow-constraint method

The application of the flow-constraint method (22) to (29) (rewritten in the DAE-form (17)) is more involved. Assuming invertibility of $J_{22}$ the flow-constraint method, as shown in detail in Appendix B, is seen to lead to the reduced model

\[
\begin{align*}
\dot{x}_1 &= [(J_s - \beta^T Z_{sk}\beta) - \beta^T Z_{sym}\beta]Q_{11}x_1 + \\
&\quad +[(-\alpha^T + \beta^T Z_{sk}\gamma^T) - (-\beta^T Z_{sym}\gamma^T)]u, \\
y_{fc} &= [(-\alpha - \gamma Z_{sk}\beta) - \gamma Z_{sym}\beta]Q_{11}x_1 + \\
&\quad +[(-\eta + \gamma Z_{sk}\gamma^T) + \gamma Z_{sym}\gamma^T]u.
\end{align*}
\]

(31)

where we have adopted the notation

\[
\begin{align*}
\alpha &:= G^T_2 J_{22}^{-1} J_{21} - G^T_1, \\
\beta &:= G^T_{R_2} J_{22}^{-1} J_{21} - G^T_{R_1}, \\
\gamma &:= G^T_2 J_{22}^{-1} G_{R_2}, \\
\delta &:= G^T_{R_2} J_{22}^{-1} G_{R_2}, \\
\eta &:= G^T_2 J_{22}^{-1} G_2, \\
Z_{sym} &:= \frac{1}{2}(Z + Z^T), \\
Z_{sk} &:= \frac{1}{2}(Z - Z^T), \\
J_s &:= J_{11} - J_{12}^{-1} J_{21}.
\end{align*}
\]

(32)
Note that even though we started with a full order port-Hamiltonian system (26) without feed-through terms, the flow-constraint method, in contrast to the effort-constraint method, results in the reduced order model (31), which is a linear input-state-output port-Hamiltonian system with feedthrough terms [3]:

\[
\begin{align*}
\dot{x}_1 &= (J_r - R_r)Q_r x_1 + (G_r - P_r)u, \\
y_{fc} &= (G_r^T + P_r^T)Q_r x_1 + (M_r + S_r)u,
\end{align*}
\]

where the reduced order matrices are

\[
\begin{align*}
J_r &= J_s - \beta^T Z_{sk} \beta, & R_r &= \beta^T Z_{sym} \beta, \\
Q_r &= Q_{11}, & G_r &= -\alpha^T + \beta^T Z_{sk} \gamma^T, \\
P_r &= -\beta^T Z_{sym} \gamma^T, & M_r &= -\eta^T + \gamma Z_{sk} \gamma^T, \\
S_r &= \gamma Z_{sym} \gamma^T.
\end{align*}
\]

One can easily verify that \(J_r, M_r\) are skew-symmetric, \(R_r, S_r\) are positive semi-definite symmetric, \(Q_r\) is positive definite symmetric, while \(R_r, P_r\) and \(S_r\) satisfy

\[
\begin{bmatrix}
R_r & P_r \\
P_r^T & S_r
\end{bmatrix} \geq 0
\]

(Lemma 1 in Appendix B demonstrates that \(Z_{sym}\) in (32) is positive definite).

**Remark 2** Whenever \(G_2 = 0\), then the reduced order port-Hamiltonian system (31) specializes to the reduced order system without feed-through terms

\[
\begin{align*}
\dot{x}_1 &= [J_s - (G_{R_1} - J_{12} J_{22}^{-1} G_{R_2})Z(G_{R_1}^T - G_{R_2}^T J_{22}^{-1} J_{21})]Q_{11} x_1 + G_1 u, \\
y_{fc} &= G_1^T Q_{11} x_1.
\end{align*}
\]

(33)

**Remark 3** In the case of a lossless full order port-Hamiltonian system (26), that is \(R = 0\) and \(\bar{R} = 0\), the reduced order port-Hamiltonian system (31) is also lossless and is given as

\[
\begin{align*}
\dot{x}_1 &= J_s Q_{11} x_1 + (G_1 - J_{12} J_{22}^{-1} G_2)u, \\
y_{fc} &= (G_1^T - G_2^T J_{22}^{-1} J_{21})Q_{11} x_1 - G_2^T J_{22}^{-1} G_2 u.
\end{align*}
\]

(34)

5.3 Effort- and flow-constraint methods in the bond-graph modeling framework

Effort- and flow-constraint methods have a direct interpretation from the bond-graph modeling point of view. Constraining the efforts

\[
e_x^2 = \frac{\partial H}{\partial x_2}(x_1, x_2) = 0, \quad e_2 = 0,
\]

\[8\]See [3] for an extensive discussion on port-Hamiltonian systems with feed-through terms
5.4 The effort-constraint method and moment matching

Consider a single-input single-output port-Hamiltonian system (26)

\[
\begin{align*}
\dot{x} &= (J - R)Qx + gu, \\
y &= g^TQx,
\end{align*}
\]

with an input matrix \( g \in \mathbb{R}^{n \times 1} \). The effort-constraint method, which leads in this case to the following reduced order model

\[
\begin{align*}
\dot{x}_1 &= F_{11}(Q_{11} - Q_{12}Q_{22}^{-1}Q_{21})x_1 + g_1u, \\
y_{ec} &= g_1^T(Q_{11} - Q_{12}Q_{22}^{-1}Q_{21})x_1,
\end{align*}
\]

turns out to have a relation to the projection based methods matching moments of the full order system at certain points in the complex plane. The moment-matching approach, discussed in [1] and the references therein, requires computing (e.g. by the Arnoldi method) a map \( V_r \in \mathbb{R}^{n \times r}, x = V_r x_r, \) with \( x_r \in \mathbb{R}^r \) being the reduced order state vector. The map \( V_r \) is used then to project the full order system (35) in such a way that \( r \) moments of (35) and the projected reduced order system match at \( s_0 \in \mathbb{C} \) or at infinity. The moment-matching approach for port-Hamiltonian systems is presented in [16, 17, 8, 24].

To illustrate the relation of the effort-constraint method to moment matching, consider a full order single-input single-output port-Hamiltonian system (35). The co-energy variable representation of (35) (with the usual coordinate
transformation $e = Qx$, see [3, 15]) will take the form
\[
\begin{align*}
\dot{e} &= Q(J - R)e + Qgu, \\
y &= g^T e.
\end{align*}
\] (37)

Recall from literature on moment matching (see again [1]) that a map $V_e \in \mathbb{R}^{n \times r}$ matches the first $r$ moments of (37) at infinity or at $s_0 \in \mathbb{C}$ if (for $A := Q(J - R)$)
\[
\begin{align*}
\text{im}V_e &= \text{im}[Qg : AQg : \ldots : A^{r-1}Qg], \\
\text{im}V_e &= \text{im}[(A - s_0I)^{-1}Qg : \ldots : (A - s_0I)^{-r}Qg].
\end{align*}
\] (38)

Then the following result holds true.

**Theorem 1** Suppose that the energy coordinates $x$ of (35) are such that the projection map
\[
V_e = \begin{bmatrix} V_1 \\ 0 \end{bmatrix}, V_1 \in \mathbb{R}^{r \times r}, V_1 \text{ - invertible.}
\]
matches the first $r$ moments at $s_0 \in \mathbb{C}$ or at infinity of the full order system in co-energy coordinates (37). Then the reduced order port-Hamiltonian model obtained by the effort-constraint method
\[
\begin{align*}
\dot{x}_1 &= F_{11}(Q_{11} - Q_{12}Q_{22}^{-1}Q_{21})x_1 + g_1u, \\
y_{ec} &= g_1^T (Q_{11} - Q_{12}Q_{22}^{-1}Q_{21})x_1,
\end{align*}
\] (39)
matches the first $r$ moments of the full order system (35) at $s_0 \in \mathbb{C}$ or at infinity.

**Proof** The moment matching projection of the rewritten port-Hamiltonian system (37)
\[
\begin{align*}
Q^{-1} \dot{e} &= (J - R)e + gu, \\
y &= g^T e,
\end{align*}
\]

is given by
\[
\begin{align*}
V_e^T Q^{-1} V_e \dot{e}_r &= V_e^T (J - R)V_e \dot{e}_r + V_e^T g, \\
\hat{y} &= g^T V_e \dot{e}_r.
\end{align*}
\] (40)

Using the well-known matrix inversion formula we get
\[
V_e^T Q^{-1} V_e = \begin{bmatrix} V_1^T \\ 0 \end{bmatrix} \begin{bmatrix} Q_s^{-1} & * \\ * & 0 \end{bmatrix} \begin{bmatrix} V_1 \\ 0 \end{bmatrix} = V_1^T Q_s^{-1} V_1,
\]

where $Q_s = Q_{11} - Q_{12}Q_{22}^{-1}Q_{21}$ is the Schur complement of $Q$. Therefore the reduced order system becomes
\[
\begin{align*}
V_1^T Q_s^{-1} V_1 \dot{e}_r &= V_1^T (J_{11} - R_{11})V_1 \dot{e}_r + V_1^T g_1u, \\
\hat{y} &= g_1^T V_1 \dot{e}_r.
\end{align*}
\]
Figure 5: n-dimensional mass-spring-damper system

Since $e = V_r e_r$ implies that $e_1 = V_1 e_r$ and since $V_1^T$ is invertible the reduced order model transforms to

$$\begin{cases} Q_{e_1}^{-1} \dot{e}_1 = (J_{11} - R_{11}) e_1 + g_1 u, \\
\hat{y} = g_1^T e_1, \end{cases}$$

which is, after the transformation from co-energy to energy coordinates $e_1 = Q_{e_1} x_1$, nothing but the reduced order system (39) obtained by the effort-constraint method

$$\begin{aligned}
\dot{x}_1 &= F_{11}(Q_{11} - Q_{12} Q_{22}^{-1} Q_{21}) x_1 + g_1 u, \\
y_{ec} &= g_1^T (Q_{11} - Q_{12} Q_{22}^{-1} Q_{21}) x_1.
\end{aligned}$$

(41)

Since there are only linear coordinate transformations involved, the moments of (41) and (40) are the same which completes the proof.

5.5 The choice of the coordinate system for model reduction

As already indicated before, we do not address in this paper the question of how to choose the coordinate system in which we apply either the effort- or the flow-constraint method. One possible choice of coordinates is balanced coordinates using Lyapunov balancing, positive real (Chapter 4 of [15]) or some other type of balancing. Another choice for the flow-constraint method would be to choose the coordinates where $G_2 = 0$, which would significantly simplify the expression of the reduced order model (31), see (33). The effort-constraint method for the SISO port-Hamiltonian systems naturally suggests coordinates $x$ as in Theorem 1 in order to match moments at specific points in the complex plane, which would pose a question of how to find such coordinates in a numerically efficient way.

6 Numerical example

Consider an $n$-dimensional full order port-Hamiltonian mass-spring-damper system as shown in Fig. 5, with masses $m_i$, spring constants $k_i$ and damping constants $c_i \geq 0$, for $i = 1, \ldots, n/2$. $p_i$ and $q_i$ are the momentum and displacement of the mass $m_i$, respectively. The external force acting on the first mass,
$m_1$, is the input $u$, while its velocity is the output $y$. State variables are defined in the following way: for $i = 1, \ldots, n/2$, $x_{2i-1} = q_i$ and $x_{2i} = p_i$. A detailed port-Hamiltonian description of this system is given in [8].

We considered a 100-dimensional mass-spring-damper system with $m_i = 1$, $k_i = 2$, and $c_i = 3.6$, and applied the effort-constraint method from (30), the flow-constraint method as in (31) and the regular balanced truncation. The coordinates chosen for reduction are (Lyapunov) balanced coordinates.

The reduced order systems are constructed for the orders $r = 2$ to $r = 30$ with increments of 2. Evolution of the relative $\mathcal{H}_2$- and $\mathcal{H}_\infty$-norms is shown in Fig. 6. The figure demonstrates that both relative norms for the effort-constraint method consistently decay as the dimension of the reduced order models increases, perhaps apart from the orders $r = 28$ and $r = 30$. The relative $\mathcal{H}_\infty$-norm for the flow-constraint method surprisingly does not show similar decaying behavior. Therefore the effort-constraint method outperforms the flow-constraint method for the considered mass-spring-damper system for all dimension of the reduced order models except for $r = 6$. The performance of the effort-constraint method was also studied in [12, 8, 15]. Note that a feed-through term is present in the flow-constraint method (31). Thus the $\mathcal{H}_2$-norms of the flow-constraint method are unbounded and are not shown in the figure.

The regular balanced truncation method, as seen from Fig. 6, outperforms the presented effort- and flow-constraint methods for all dimensions of the reduced order models. Yet we want to underline that the balanced truncation method does not preserve the port-Hamiltonian structure (as explained in [15], Remark 2.12).

The amplitude Bode plots of the full, reduced and error systems for $r = 10$.
are shown in Fig. 7. The figure exhibits that the approximation by the flow-constraint method is better for low frequencies, while the approximation by the effort-constraint method does a better job for high frequencies. The error plot illustrates that the $H_\infty$-norm is larger for the reduced model by the flow-constraint method. This is consistent with the information from Fig. 6.

Naturally, the considered reduced order models produced by the effort- and flow-constraint methods inherit the port-Hamiltonian structure, are asymptotically stable and passive.

7 Conclusions

In this paper we considered two port-Hamiltonian structure preserving model reduction methods: the effort-constraint method and the flow-constraint method. These methods arise from the geometric description of general port-Hamiltonian systems and are based on the idea of replacing the interconnections to the energy-storage which carry little power by zero-power constraints. These constraints can be interpreted within the bond-graph modeling framework as effort- or flow-constraints. We showed that the effort-constraint method, applied in particular coordinates, matches the first moments of the SISO full order port-Hamiltonian system at specific points in the complex plane. A numerical ex-
ample illustrates the performance of the effort- and flow-constraint methods. A systematic way of choosing the coordinates for the full order port-Hamiltonian system in order to obtain the most accurate approximation from the input-output point of view, and possible error bounds for the effort-constraint and flow-constraint methods, are questions for future research.

A Effort-constraint reduction

Consider the full order port-Hamiltonian system (29) with a splitting of the state according to the dimension $r$ chosen for the reduced order model:

\[
\begin{align*}
\begin{bmatrix}
\dot{x}_1 \\
\dot{x}_2 
\end{bmatrix} &=
\begin{bmatrix}
J_{11} & J_{12} \\
J_{21} & J_{22}
\end{bmatrix}
\begin{bmatrix}
Q_{11} & Q_{12} \\
Q_{21} & Q_{22}
\end{bmatrix}
\begin{bmatrix}
x_1 \\
x_2
\end{bmatrix} +
\begin{bmatrix}
G_{R_1} \\
G_{R_2}
\end{bmatrix} f_R +
\begin{bmatrix}
G_1 \\
G_2
\end{bmatrix} u,
\end{align*}
\]

\[
y = [G^T_1 G^T_2]
\begin{bmatrix}
Q_{11} & Q_{12} \\
Q_{21} & Q_{22}
\end{bmatrix}
\begin{bmatrix}
x_1 \\
x_2
\end{bmatrix},
\tag{42}
\]

\[
\begin{bmatrix}
e_R \\
f_R
\end{bmatrix} = [G^T_{R_1} G^T_{R_2}]
\begin{bmatrix}
Q_{11} & Q_{12} \\
Q_{21} & Q_{22}
\end{bmatrix} f_R, \quad f_R = -\bar{R} e_R.
\]

The full order Dirac structure corresponding to the model (42) is given by the explicit equation in the DAE form (17)

\[
F_x \dot{x} = E_x \frac{\partial H}{\partial x}(x) + F_R f_R + E_R e_R + F_P f_P + E_P e_P,
\tag{43}
\]

or

\[
\begin{bmatrix}
I_n & 0 \\
0 & I_{n-r}
\end{bmatrix}
\begin{bmatrix}
\dot{x}_1 \\
\dot{x}_2
\end{bmatrix} =
\begin{bmatrix}
J_{11} & J_{12} \\
J_{21} & J_{22}
\end{bmatrix}
\begin{bmatrix}
Q_{11} & Q_{12} \\
Q_{21} & Q_{22}
\end{bmatrix}
\begin{bmatrix}
e_1 \\
e_2
\end{bmatrix} +
\begin{bmatrix}
G_{R_1} \\
G_{R_2}
\end{bmatrix} f_R +
\begin{bmatrix}
G_1 \\
G_2
\end{bmatrix} u +
\begin{bmatrix}
0_{n \times m} \\
0_{m \times n}
\end{bmatrix} e_R +
\begin{bmatrix}
0_{n \times m} \\
0_{m \times n}
\end{bmatrix} e_P,
\tag{44}
\]

where $m_R$ is the dimension of the vector of resistive variables $f_R$, $e_R$, and $m$ is that of the vectors of input and output variables $f_P = u$, $e_P = y$.

Using the notation $e_x = \frac{\partial H}{\partial x}(x)$, the above equation reads

\[
\begin{bmatrix}
I_n & 0 \\
0 & I_{n-r}
\end{bmatrix}
\begin{bmatrix}
\dot{x}_1 \\
\dot{x}_2
\end{bmatrix} =
\begin{bmatrix}
J_{11} & J_{12} \\
J_{21} & J_{22}
\end{bmatrix}
\begin{bmatrix}
Q_{11} & Q_{12} \\
Q_{21} & Q_{22}
\end{bmatrix}
\begin{bmatrix}
e_1 \\
e_2
\end{bmatrix} +
\begin{bmatrix}
G_{R_1} \\
G_{R_2}
\end{bmatrix} f_R +
\begin{bmatrix}
G_1 \\
G_2
\end{bmatrix} u +
\begin{bmatrix}
0_{n \times m} \\
0_{m \times n}
\end{bmatrix} e_R +
\begin{bmatrix}
0_{n \times m} \\
0_{m \times n}
\end{bmatrix} e_P.
\]
Recall from Section 4 that the effort-constraint method assumes finding a (non-unique) maximal rank matrix $L_{ec}$ satisfying

$$L_{ec} F_x = 0,$$

as well as setting $e_x^2 = 0$. The simplest choice for $L_{ec}$ is

$$L_{ec} = \begin{bmatrix} I_r & 0 & 0 \\ 0 & I_m & 0 \\ 0 & 0 & I_{m_R} \end{bmatrix}. \quad (45)$$

Premultiplying (44) with $L_{ec}$, while setting $e_x^2 = 0$, leads to

$$\begin{bmatrix} I_r \\ 0_{m_R \times r} \end{bmatrix} \dot{x}_1 = \begin{bmatrix} J_{11} \\ -G_{11}^T \\ -G_{11}^T R_{11} \end{bmatrix} e_x^1 + \begin{bmatrix} 0_{m_R \times m_R} \\ 0_{m_R \times m} \end{bmatrix} f_R + \begin{bmatrix} 0_{r \times m_R} \\ 0_{m_R \times m} \end{bmatrix} e_R + \begin{bmatrix} G_{11} \\ 0_{m \times m} \end{bmatrix} u + \begin{bmatrix} 0_{m \times m} \\ 0_{m_R \times m} \end{bmatrix} \hat{y}, \quad (46)$$

which is the equational representation (20)

$$L_{ec} F_x^1 f_x^1 + L_{ec} E_x^1 e_x^1 + L_{ec} F_R f_R + L_{ec} E_R e_R + L_{ec} F_P f_P + L_{ec} E_P e_P = 0,$$

of the reduced order Dirac structure (note that $f_x^1 = -\dot{x}_1$).

Recall from [15] (Section 2.6.1) that setting $e_x^2 = 0$ implies that $e_x^1 = Q_s x_1$, where $Q_s = Q_{11} - Q_{12} Q_{22}^{-1} Q_{21}$ is the Schur complement of the energy matrix $Q$. The equational representation (46) is hence equivalent to

$$\begin{cases} \dot{x}_1 = J_{11} Q_s x_1 + G_{R1} f_R + G_{11} u, \\ \hat{y} = G_{11}^T Q_s x_1, \\ e_R = G_{R1}^T Q_s x_1. \end{cases} \quad (47)$$

This is the reduced order port-Hamiltonian model by the effort-constraint method with the open resistive port. Termination of the resistive port employing the original linear relation $f_R = -\dot{R} e_R$ (while using $R_{11} = G_{R1} R_{R1}$, after the corresponding splitting of $R$ from (28)) leads to the reduced order port-Hamiltonian model by the effort-constraint method (30)

$$\begin{cases} \dot{x}_1 = (J_{11} - R_{11})(Q_{11} - Q_{12} Q_{22}^{-1} Q_{21}) x_1 + G_{11} u, \\ y_{ec} = G_{11}^T (Q_{11} - Q_{12} Q_{22}^{-1} Q_{21}) x_1. \end{cases} \quad (48)$$

### B Flow-constraint reduction

We start with the equational representation of the full order Dirac structure (44). A maximal rank matrix $L_{fc}$ satisfying

$$L_{fc} F_x = 0$$

...
which, after substituting in the other equations and using the fact that

the equations by $L^c$ and setting $f_2^T = -\dot{x}_2 = 0$ leads to the following equational representation of the reduced order Dirac structure

\[
\begin{bmatrix}
I_r & -J_{12}J_{22}^{-1} \\
G_{T} & G_{T} & J_{22}^{-1} & 0 \\
G_{T} & G_{T} & J_{22}^{-1} & 0 \\
0 & G_{T} & J_{22}^{-1} & 0
\end{bmatrix}
\begin{bmatrix}
\dot{x}_1 \\
\dot{x}_2 \\
\dot{x}_3 \\
\dot{x}_4
\end{bmatrix}
= \begin{bmatrix}
J_s & G_{T} & J_{22}^{-1} & 0 \\
G_{T} & G_{T} & J_{22}^{-1} & 0 \\
G_{T} & G_{T} & J_{22}^{-1} & 0 \\
0 & G_{T} & J_{22}^{-1} & 0
\end{bmatrix}
\begin{bmatrix}
e_1^T \\
e_2^T
\end{bmatrix}
+ \begin{bmatrix}
G_{R_1} - J_{12}J_{22}^{-1}G_{R_2} \\
G_{T} & G_{T} & J_{22}^{-1} & 0 \\
G_{T} & G_{T} & J_{22}^{-1} & 0 \\
0 & G_{T} & J_{22}^{-1} & 0
\end{bmatrix}f_R + \begin{bmatrix}
0_{r \times m}\Gamma \\
0_{m \times m}
\end{bmatrix}e_R + \begin{bmatrix}
G_1 - J_{12}J_{22}^{-1}G_2 \\
G_{T} & G_{T} & J_{22}^{-1} & 0 \\
G_{T} & G_{T} & J_{22}^{-1} & 0 \\
0 & G_{T} & J_{22}^{-1} & 0
\end{bmatrix}u + \begin{bmatrix}
0_{r \times m}\Gamma \\
0_{m \times m}
\end{bmatrix}\gamma.
\]

Using the notation as in (32)

\[
\alpha := G_{T}J_{22}^{-1}J_{21} - G_{T}, \quad \beta := G_{T}J_{22}^{-1}J_{21} - G_{T},
\]

\[
\gamma := G_{T}J_{22}^{-1}G_{R_2}, \quad \delta := G_{T}J_{22}^{-1}G_{R_2},
\]

\[
\eta := G_{T}J_{22}^{-1}G_2,
\]

the above equation takes the form

\[
\begin{bmatrix}
I_r \\
0_{m \times r}
\end{bmatrix} \begin{bmatrix}
\dot{x}_1 \\
\dot{x}_2 \\
\dot{x}_3 \\
\dot{x}_4
\end{bmatrix}
= \begin{bmatrix}
J_s & -\beta^T \\
\alpha & \gamma
\end{bmatrix} \begin{bmatrix}
e_1^T \\
e_2^T
\end{bmatrix}
+ \begin{bmatrix}
0_{r \times m}\Gamma \\
0_{m \times m}
\end{bmatrix}e_R + \begin{bmatrix}
0_{r \times m}\Gamma \\
0_{m \times m}
\end{bmatrix}e_R + \begin{bmatrix}
0_{r \times m}\Gamma \\
0_{m \times m}
\end{bmatrix}u + \begin{bmatrix}
0_{r \times m}\Gamma \\
0_{m \times m}
\end{bmatrix}\gamma.
\]

The equational representation (50) of the reduced order Dirac structure implies the reduced order port-Hamiltonian model

\[
\begin{cases}
\dot{x}_1 = J_x e_1^T - \beta^T f_R - \alpha T u, \\
\dot{y} = -\alpha e_1^T - \gamma f_R - \eta u, \\
0 = \beta e_1^T + \delta f_R + \epsilon_R - \gamma T u.
\end{cases}
\]
such that $e_1^T = Q_{11}x_1$ ($\dot{x}_2 = 0$ implies $x_2 = \text{constant}$ taken to be zero), results in the reduced order port-Hamiltonian model (31)

$$
\begin{align*}
\dot{x}_1 &= (J_s - \beta^T Z \beta)Q_{11}x_1 + (-\alpha^T + \beta^T Z \gamma^T)u, \\
y_{f,c} &= (-\alpha - \gamma Z \beta)Q_{11}x_1 + (-\eta + \gamma Z \gamma^T)u,
\end{align*}
$$

where $Z = \bar{R}(I - \delta R)^{-1}$.

Finally, we prove that the symmetric part of the matrix $Z$ is positive-definite, showing that the reduced order model obtained by the flow-constraint method is indeed port-Hamiltonian.

**Lemma 1** Consider the matrix $Z$ from (32) given as

$$Z := \bar{R}(I - \delta R)^{-1}$$

for a skew-symmetric matrix $\delta = -\bar{\delta}^T = \bar{G}_{R_2}J_{22}^T \bar{G}_{R_1}$, and a symmetric positive definite matrix $\bar{R} = \bar{R}^T > 0$. Then the matrix $Z$ can be decomposed into its symmetric $Z_{sym}$ and skew-symmetric $Z_{sk}$ parts as follows:

$$Z_{sym} = (\bar{R}^{-1} - \delta \bar{R} \delta)^{-1}, \quad Z_{sk} = (\bar{R}^{-1} \delta^{-1} \bar{R}^{-1} - \delta)^{-1}.$$

Furthermore, the symmetric part of the matrix $Z$ is positive definite:

$$Z_{sym} = (\bar{R}^{-1} - \delta \bar{R} \delta)^{-1} > 0.$$

**Proof 1** The matrix $Z$ can be rewritten as $Z = (\bar{R}^{-1} - \delta)^{-1}$. Then straightforward calculations show that

$$Z_{sym} = \frac{1}{2}(Z + Z^T) = \frac{1}{2}[(\bar{R}^{-1} - \delta)^{-1} + (\bar{R}^{-1} + \delta)^{-1}],$$

$$= \frac{1}{2}(\bar{R}^{-1} - \delta)^{-1}[(\bar{R}^{-1} + \delta)(\bar{R}^{-1} + \delta)^{-1} - (\bar{R}^{-1} + \delta)^{-1} - (\bar{R}^{-1} - \delta)(\bar{R}^{-1} - \delta)^{-1} - (\bar{R}^{-1} - \delta)^{-1}(\bar{R}^{-1} - \delta)^{-1} - (\bar{R}^{-1} - \delta)^{-1}(I + \delta \bar{R})^{-1} - [(I + \delta \bar{R})(\bar{R}^{-1} - \delta)]^{-1} - (\bar{R}^{-1} - \delta \bar{R} \delta)^{-1}.$$

Similarly

$$Z_{sk} = \frac{1}{2}(Z - Z^T) = (\bar{R}^{-1} \delta^{-1} \bar{R}^{-1} - \delta)^{-1}.$$

Moreover, $Z = (\bar{R}^{-1} - \delta)^{-1}$ implies that $Z^{-1} = \bar{R}^{-1} - \delta$. Hence, the symmetric part of $Z^{-1}$, which is $\bar{R}^{-1}$, is necessarily positive definite.

Since any real vector $w$ can be written as $w = Z^{-1}v$ for a certain $v$, it follows that

$$w^T Z w = v^T Z^{-T} Z Z^{-1} v = v^T Z^{-T} v = v^T Z^{-1} v > 0.$$

This proves that the symmetric part of $Z$ is positive definite.

Finally note that in the case of a lossless full order port-Hamiltonian system $\bar{R} = 0$ and, consequently, $Z = 0$.
