Publisher Version:
Publisher's PDF, also known as Version of Record (includes final page, issue and volume numbers)

Please check the document version of this publication:

• A submitted manuscript is the version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.
• The final author version and the galley proof are versions of the publication after peer review.
• The final published version features the final layout of the paper including the volume, issue and page numbers.

Remodeling of the collagen architecture in cardiovascular tissues

N.J.B. Driessen, M.A.J. Cox, C.V.C. Bouten and F.P.T. Baaijens
Eindhoven University of Technology, Department of Biomedical Engineering

Introduction
To optimize mechanical conditioning protocols of tissue-engineered (TE) load bearing cardiovascular constructs, a mathematical model is developed that relates changes in the collagen architecture (i.e., remodeling) to the local mechanical condition within the tissue. The model is applied to predict the typical collagen architecture present in arteries and aortic valves (Fig. 1).

Materials and methods
The tissues are modeled as incompressible fiber reinforced materials and a structurally-based constitutive model is used that enables incorporation of the angular distribution of collagen fibers [3]. The in-plane distribution of fiber volume fractions ($\phi_f$) is modeled by a periodic version of the normal probability distribution function:

$$
\phi_f(\gamma) = A \exp \left[ \frac{\cos [2(\gamma - \alpha)] + 1}{\beta} \right] \tag{1}
$$

with $\gamma$ the in-plane angle, $\alpha$ the main fiber angle and $\beta$ the dispersity of the fiber distribution function. Stimulus functions ($g_1$ and $g_2$) in the principal directions ($v_1$ and $v_2$) are introduced to specify the value of the main fiber angle and the dispersity:

$$
\alpha = \arctan(g_2/g_1) \tag{2}
$$

$$
\beta = \left\{ \begin{array}{ll}
\frac{A}{(g_1/g_2)^{-1}} & \text{for } g_1 \geq g_2 \\
\frac{A}{(g_2/g_1)^{-1}} & \text{for } g_1 < g_2
\end{array} \right. \tag{3}
$$

The stimulus functions are assumed to depend on the mechanical loading condition within the tissue, i.e., $g_i = g_i(\lambda, \sigma)$. The stimulus functions are specified such that: (1) for a uniaxial loading condition all fiber directions align with the major loading direction, (2) in case of a biaxial loading condition, the fiber families are situated in between the major directions with the main orientation and dispersity depending on the ratio of $g_1$ and $g_2$, and (3) for an equibiaxial loading condition, the fibers are distributed uniformly in the plane of the major directions $v_1$ and $v_2$.

Results
The predicted fiber directions in the arterial wall represent helical paths. The pitch of the helix and the dispersity of the fiber distribution increases from the inner wall towards the outer wall (Fig. 2), in accordance with observations from literature.

Discussion
The model considers the interaction between 1) the mechanical loading condition within the tissue and 2) changes in the collagen fiber architecture. The predicted collagen architecture is qualitatively consistent with experimental observations from literature. Experiments have to be performed to further validate the model quantitatively.
