Document Version:
Publisher’s PDF, also known as Version of Record (includes final page, issue and volume numbers)

Please check the document version of this publication:
• A submitted manuscript is the version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.
• The final author version and the galley proof are versions of the publication after peer review.
• The final published version features the final layout of the paper including the volume, issue and page numbers.

Lighting, energy and safety perceptions

Street lighting is associated with energy waste and luminous pollution. Luminaires based on Light Emitting Diodes (LEDs) can reduce a city’s energy consumption, but only to a certain extent. Further savings can be achieved by dimming the lights during certain parts of the night, but there is a tradeoff between energy saving and feelings of safety (see Fig. 1). Such tradeoffs can be avoided by integrating sensing technologies to recognize the number, type, and location of road users. The resulting system can adapt continuously to the environment and provide lighting only when and where it is needed most (i.e., intelligent selective dimming; see Fig. 1). As such these intelligent dynamic street lighting systems offer a promising solution to avoid energy consumption and luminous pollution without affecting people’s sense of perceived personal safety at night.

Such solution, however, raises important new questions. For example, we need not only consider how much lighting people need in order to feel safe, but also when and where people benefit most from street lighting (e.g., in their immediate surroundings or in the road ahead?). In other words, implementing intelligent dynamic street lighting requires a better understanding of how lighting affects perceived personal safety at night.

Research goals

The main goal of the current project is to understand how street lighting affects pedestrian’s sense of safety at night. What, for example, is the relationship between the objective characteristics of street lighting and the psychological determinants of perceived personal safety? A specific secondary goal of the project is the translation of research findings and theoretical insights into requirements and implications for designing intelligent dynamic road lighting systems.

Research strategies

To meet the project goals, we combine user evaluations of different street lighting scenarios (i.e., system behaviors) with psychological experimentation. Controlled manipulation of lighting and street characteristics, either in virtual or real environments (e.g., test bed the Zaale on the university campus) allows us to test various dynamic lighting scenarios (e.g. changes in lighting distribution, illuminance, or color temperature) with respect to pedestrians’ appraisal of them in terms of perceived safety. Important theoretical insights may also be gained from user observations in real or virtual settings (e.g. involving eye-tracking to learn more about users’ scan paths and the relevant objects and areas that should be lit), or from testing specific motivational, cognitive and affective mechanisms through which road lighting possibly affects perceived safety (e.g. need for control, emotional states such as fear, or travel goals).

Acknowledgement

This research is part of the ISLES 2014 project in which partners from industry (Philips and several SMEs) collaborate with TU/e as the scientific research partner. ISLES 2014 is funded by AgentschapNL under the Point One scheme.
