Publisher's PDF, also known as Version of Record (includes final page, issue and volume numbers)

Please check the document version of this publication:

- A submitted manuscript is the version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.
- The final author version and the galley proof are versions of the publication after peer review.
- The final published version features the final layout of the paper including the volume, issue and page numbers.

Ultrasound flow assessment in curved vessels: an in-vitro study

Bart Beulen, Marcel Rutten, Frans van de Vosse

Introduction

Ultrasonic perpendicular velocimetry (UPV) (Fig. 1) allows a simultaneous assessment of axial velocity profile and wall position in straight vessels, enabling an accurate flow estimation [1].

Fig. 1 Schematic overview of UPV.

However, in-vivo, most arteries are curved, causing transversal velocity components, which can have an adverse effect on the performance of UPV. Additionally, the presently applied Poiseuille and Womersley approximations offer a poor estimate for the asymmetrical axial velocity distribution, resulting in inaccurate flow estimations.

Objective

Validate UPV for instationary non-Newtonian flow in a curved geometry. Estimate the volume flow from the assessed asymmetrical velocity profiles and compare the results with the Poiseuille and Womersley approximations.

Methods

In the experimental setup, a physiologically relevant flow pulse is applied to a curved vessel phantom (Fig. 2). The employed fluid mimics the acoustic and viscoelastic properties of blood.

Fig. 2 Ultrasound probe positioned perpendicular to the vessel.

The axial velocity distribution is determined by UPV using a linear array probe and subsequently integrated to yield the flow rate [2]. Simultaneously, the flow rate is measured directly. A finite-element CFD model of a rigid walled curved vessel is applied to

calculate the time-dependent velocity distribution.

Results

Velocity profiles

Fig. 3 Comparison of the UPV measurement ($\circ$) and the CFD calculated velocity profiles ($-$).

Flow rates

Fig. 4 Comparison of the reference flow measurement and the UPV, Poiseuille and Womersley based flow approximations.

For UPV, the average deviation with respect to the reference flow is about 5%, compared to an average deviation of 20% for both the Poiseuille and Womersley approximations.

Conclusions

The UPV method allows an accurate assessment of the axial velocity distribution in a curved vessel. For volume flow estimation it is found that the UPV based flow estimate is far more accurate than the existing Poiseuille and Womersley approximations.
