Document Version:
Publisher’s PDF, also known as Version of Record (includes final page, issue and volume numbers)

Please check the document version of this publication:

• A submitted manuscript is the version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher’s website.
• The final author version and the galley proof are versions of the publication after peer review.
• The final published version features the final layout of the paper including the volume, issue and page numbers.

Simulation of ParticleFilledViscoelastic Flows usingGrid Deformation Methods

Y. J. Choi, M. A. Hulsen and H. E. H. Meijer
Materials Technology, Eindhoven University of Technology

Introduction
The presence and the motion of particles in fluids is ubiquitous in our everyday life, both in nature and in technology. In fluid-particle systems, the apparent properties of suspensions depend on the spatial distribution of particles. In viscoelastic fluids, the distribution of particles is not uniform even if particles are uniformly distributed initially. Hence, we want to know the evolution of multi-particle structures and the mechanisms that induce particle migration especially in polymeric fluids.

Numerical Methods
For the direct numerical simulation of fluid-particle systems we developed a finite element program using fictitious domain methods [1]. The basic idea of the fictitious domain method is that the rigid body is filled with the surrounding fluid and it is assumed that the fluid inside each particle moves like a rigid body. By using this method, we can eliminate the need for remeshing at each time step (Fig. 1(b)). However, to obtain accurate solutions of fluid-particle motions, very fine meshes are needed along the fluid-particle interface which requires huge computational cost. To overcome this problem, we adopted grid deformation methods to obtain mesh refinements only local to the interface, reducing the number of elements needed (Fig. 1(c)) [2].

Example: Cavity Flow
A unit square domain is filled with a viscoelastic fluid and a unit driven velocity is applied of the top plate. An Oldroyd-B constitutive model with two viscoelastic modes is used ($\eta_p = 1.0$, $\eta_s = \{0.8, 0.5\}$, $\lambda = \{1.0, 0.4\}$). Initially, a particle of radius $r = 0.1$ is positioned in the middle of the square domain (Fig. 2).

Results
For the simulation of this problem, we used three different meshes - ① a coarse 50×50 regular mesh, ② a fine 100×100 regular mesh and ③ a deformed mesh based on the coarse 50×50 mesh. The results with grid deformation methods are almost the same as the results of a twice finer regular mesh (Fig. 3). However, the computation time and the memory needed are much less than for the finer regular mesh (Tab. 1).

Conclusions
- A viscoelastic particulate flow analysis program has been implemented using fictitious domain methods and grid deformation methods.
- Comparably accurate particle motions are obtained with less computation time and memory compared with the results using a finer regular mesh.
