**Introduction**

To assess the physiological significance of coronary artery disease (CAD) and distinguish between epicardial and microvascular disease (Fig. 1) simultaneous measurement of intracoronary pressure and flow is required [1,2].

![Figure 1](image1.png)

**Objective**

The objective of this study is to enable flow measurement by adapting a commercially available pressure-sensing guidewire, the Radi PressureWire (right side of Fig. 1), so it can function as a constant temperature hot film anemometer. This will enable assessment of intracoronary pressure and flow using a single guidewire.

**Material and Methods**

**Hot film anemometry**

A small temperature sensitive resistor, which is part of the PressureWire, is electrically heated to a constant temperature. The amount of heat transferred to the surrounding fluid is influenced by the local flow rate. Therefore, the power (P) needed to keep the resistor at a constant temperature is a measure for the flow (Q). The relationship between power and flow is characterized by a power law model [3]:

\[
P = P_0 + P_1 \left( \frac{Q}{Q_0} \right)^n,
\]

where the parameters \( P_0, P_1, Q_0 \) and \( n \) depend on the geometry of the sensor, temperature and the flow signal.

**Experimental set-up**

The PressureWire is tested in an open loop circulation inside a temperature controlled water bath (Fig. 2). The flow through the circulation is controlled by a piston pump and measured by the PressureWire and a reference flow meter.

![Figure 2](image2.png)

**Results**

**Mean flow assessment**

The left side of Figure 3 shows the relationship between mean power and mean flow for an overheating of 20 K. It is represented as the standard deviation of five measurements. A curve is fitted using a power law model. Using this curve the flow is calculated and presented with a Bland-Altman plot (right side of Fig. 3).

![Figure 3](image3.png)

**Dynamic flow assessment**

Figure 4 shows that a flow signal, similar to a coronary flow, can be tracked in time.

![Figure 4](image4.png)

**Conclusions**

Reproducible calibration curves for mean flow measurement could be obtained for an overheating of 20 K. The relationship between power and flow could be described with a power law model. This method is promising for the assessment of both pressure and flow using a single guidewire. Furthermore, since the phasic pattern of the flow can be measured, this sensor might even be suitable for the search for new parameters, indicating CAD, based on dynamic pressure and flow.
