Structure-property modeling of low-alloyed TRIP steels

S.P. Chen, V. Kouznetsova, M.G.D. Geers

Introduction
Transformation Induced Plasticity (TRIP) is a phenomenon which occurs during solid phase transformation triggered by an applied mechanical load, and which causes irreversible strains at stress levels that are below the current yield stress of the softer phase. Low alloyed multi-component TRIP steels present a unique combination of high ductility and strength, which comes from both TRIP and the synergy between the properties of multicomponents. The aim is to develop a physically-based, multi-scale model to predict the structure-property relations in the TRIP steels (Fig.1).

Methods
- Develop a model for martensitic transformation in TRIP steel in a thermodynamically based continuum mechanics framework at large strains.
- Incorporate the model in a hierarchical micro-macro computational homogenization strategy [1].

Miromechanical model
The transforming microstructure is considered as a rank-one laminate composed of a martensite plate and an austenite layer. The total deformation gradient tensor, $F$, at a transforming region is assumed to be known. The evolution of martensitic volume fraction and the constitutive behavior of the transforming region can be obtained by solving the following equation system:

$$\begin{align*}
F_{\text{tr}} &= I + \tilde{M} \otimes \tilde{N} \\
F_A \cdot (I - \tilde{N} \otimes \tilde{N}) &= F_M \cdot (I - \tilde{N} \otimes \tilde{N}) \\
(P_A - P_M) \cdot \tilde{N} &= 0
\end{align*}$$

$F_i$, Piola-Kirchhoff stress tensor, $B^c_i$, the elastic left Cauchy-Green deformation tensor, $\tau_i$, the Kirchhoff stress tensor, $C_i$, a fourth-order tensor of material constant, $\Delta \gamma_i$, the increment of the plastic flow, $G$ the thermodynamic driving force, $(P) = (P_A + P_M)/2$, $[F] = F_A - F_M$, $[\Phi]$ the jump of Helmholtz free energy at the interface, $G_c$, a critical barrier.

Results
The model is applied to a single crystal austenite colony to characterize the TRIP effect. Evolution of the martensitic volume fraction under different shear deformation modes is shown in fig. 2.

Future work
Multi-variant martenstic transformation in a meso level will be considered. The model will be incorporated in a hierarchical micro-macro computational homogenization strategy.
