Publisher's PDF, also known as Version of Record (includes final page, issue and volume numbers)

Please check the document version of this publication:
• A submitted manuscript is the author's version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.
• The final author version and the galley proof are versions of the publication after peer review.
• The final published version features the final layout of the paper including the volume, issue and page numbers.

Modeling the mechanics of human tissue-engineered heart valve leaflets

Eindhoven University of Technology, Department of Biomedical Engineering

Introduction

Computational models provide valuable information to assess the mechanics of tissue-engineered (TE) constructs. In this study, a structurally based model for collagenous cardiovascular tissues [1] is applied to evaluate the mechanical behavior of TE heart valve leaflets [2]. A recently published model for arterial wall mechanics [3] is extended with a fiber volume fraction [4] to describe the relative amount of fibers present in each direction. In this way, structural information with respect to the tissue’s fiber architecture can be incorporated.

Materials and methods

The tissues are modeled as incompressible fiber reinforced materials and the extra stress ($\tau$) is written as:

$$\tau = \hat{\tau} + \sum_{i=1}^{N} \phi_f^i (\psi_f^i - \hat{\varepsilon}_f^i \cdot \hat{\tau} \cdot \hat{\varepsilon}_f^i)$$

with $\hat{\tau}$ the (isotropic) matrix stress, $\phi_f^i$ the fiber content, $\psi_f^i$ the fiber stress, and $\hat{\varepsilon}_f^i$ the fiber direction [1]. The in-plane angular fiber distribution is described by a Gaussian function:

$$\phi_f^i(\gamma_i) = A \exp\left[-\frac{(\gamma_i - \mu)^2}{2\sigma^2}\right]$$

with $A$ a scaling factor and $\mu$ the mean value and $\sigma$ the standard deviation of the fiber distribution. $\gamma_i$ denotes the in-plane angle of the fibers, where $\gamma_i = 0^\circ$ corresponds to the circumferential direction and, consequently, $\gamma_i = 90^\circ$ coincides with the radial direction of the leaflets. The fiber direction in the undeformed configuration is written as:

$$\hat{\varepsilon}_f^i(\gamma_i) = \cos(\gamma_i)\hat{v}_1 + \sin(\gamma_i)\hat{v}_2$$

with $\hat{v}_1$ and $\hat{v}_2$ the circumferential and radial direction, respectively.

Results

The simulated distributions of the major principal stretches and stresses in the TE heart valve leaflets after pressure application are shown in Fig. 3. Compared to native leaflets, the response of the TE leaflet is (a) less nonlinear, (b) less anisotropic, (c) stiffer, and (d) there is less coaptation due to the absence of large radial strains [5].

Discussion

- The constitutive model fits the experimental data very well.
- The presented computational framework enables us to estimate the required pressure levels in a bioreactor system to obtain the desired amount of strains in TE leaflets.
- The method offers possibilities to investigate the interrelation between mechanical conditioning and tissue remodeling [6].
