Publisher’s PDF, also known as Version of Record (includes final page, issue and volume numbers)

Please check the document version of this publication:
• A submitted manuscript is the author's version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.
• The final author version and the galley proof are versions of the publication after peer review.
• The final published version features the final layout of the paper including the volume, issue and page numbers.

/Introduction
Most semi-crystalline polymers are ductile, but start to behave brittle under severe conditions: high deformation rate and low temperature. It is known that the impact toughness of semi-crystalline polymers can both be increased by addition of rubber particles as well as certain hard filler particles.

Advantage of system with hard filler compared to rubber filler:
• Increased stiffness
• No influence $T_g$ rubber phase

Toughening mechanism
Recently a toughening mechanism for these heterogeneous semi-crystalline polymer systems was postulated by A.S. Argon (MIT) [1-3]. It is based on the idea that an interface is formed around the inclusions (rubber or hard filler), which consists of preferentially oriented crystalline lamellae, having a reduced plastic shear resistance in the crystal planes parallel to the filler surface.

Upon cavitation or debonding of particles → large shear deformation of ligaments between particles

If oriented lamellae bridge between particles → low shear resistance behaviour percolates throughout structure and toughness is enhanced.

Objective
The goal is to verify this toughening mechanism. The first step is to find the existence and mechanical behaviour of this anisotropic crystal oriented layer.

/Materials and Methods
Using a multiflux static mixer sub-micron multi layer systems can be made consisting of alternating layers of a semi-crystalline polymer (HDPE) and a substrate polymer (SEBS & SBS):

5 to 10 mixing elements
64 to 2048 layers
Layer thickness: 16 $\mu$m to 0.2 $\mu$m

The crystal orientation was investigated by X-ray diffraction and Transmission Electron Microscopy.

/Results
Wide Angle X-ray Diffraction patterns:

- Thick HDPE layers show no crystal orientation → isotropic spherulites
- Thin HDPE layers show orientation of the 200 (∥ to surface) and 110 ($\pm 30^\circ$ to 200) crystal planes → lamellae ⊥ to surface

TEM confirms lamellae orientation in HDPE near the substrate.

Conclusion: So far the results support the postulated toughening mechanism.

/Future Work
- Determine thickness of crystal oriented layer more accurate
- Exploitation towards other materials
- Determine mechanical behaviour of anisotropic crystalline layer
