Publisher’s PDF, also known as Version of Record (includes final page, issue and volume numbers)

Please check the document version of this publication:
• A submitted manuscript is the version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.
• The final author version and the galley proof are versions of the publication after peer review.
• The final published version features the final layout of the paper including the volume, issue and page numbers.

SIMULATION OF CELL DEFORMATION IN A MICROFLUIDIC CROSS-SLOT DEVICE

Guansheng Du¹,²,³, Qun Fang², Jaap den Toonder*¹,³

Introduction
It is well known that a number of serious diseases affect the mechanical properties of cells, e.g., cancer, malaria, cardiac myopathy. The ability to measure cell mechanical properties, therefore, could provide a good diagnosis method. We propose a special microfluidic device, in which a fluid flow provides the hydrodynamic force that deforms the cells. The measurement of the extent of deformation enables to estimate the cell stiffness. The aim of our study is to investigate the effectiveness of approach, and to obtain an optimized design of the cross-slot geometry.

The device principle
Our basic microfluidic device is a cross-slot device. It contains two fluid inlets and two fluid outlets. A cell is positioned at the center and fixed there by continuous control of the pressures at the two inlets. The cell experiences an elongational flow that deforms it.

Computational methods
We carried out finite element method software Comsol to calculate the pressure and stress distribution around the cell boundary at different conditions. The solution was then transformed to MATLAB, in which the cell deformation was calculated as a standard linear solid [1]. To quantify the deformation, we use the so-called Taylor deformation parameter:

\[ D_{xy} = \frac{Y - Y'}{Y + Y'} \]

where the \( X \) and \( Y \) are the cell radius in the x-direction and y-direction, which are time-dependent.

The channel structures (Fig.1) are based on the cross-slot. To obtain better cell deformation and cell control results, two improved structures were also investigated.

Figure 1: The cross slot designs used in the simulation. Design A: channel width and height are both 40 \( \mu \)m. Design B: the width is 50 \( \mu \)m, which is gradually narrowed to 15 \( \mu \)m in the x-direction and to 30 \( \mu \)m in the y-direction. Design C: channel width is 50 \( \mu \)m, narrowed to 15 \( \mu \)m in the x-direction, and the outlet channels in the y-direction contain obstructions.

Computational results
We set a reference condition in our calculation, in which the inlet velocity is 10 mm/s, the liquid has density 1000 kg/m³ and viscosity 1 mPa·s the channel height and width are both 40 \( \mu \)m. We choose endothelial cell as our reference cell, whose radius is 7.5 \( \mu \)m, with elastic constants \( K_1 = 22.5 \) Pa, \( K_2 = 37.5 \) Pa, and viscosity \( \eta = 1.7 \times 10^3 \) Pa·s [1]. Both the cell and liquid are incompressible. The reference result is the red line in the following pictures.

![Figure 2: The deformation \( D_{xy} \) as a function of time for six different designs. Design 1-4 are on the basis of structure A, but the channel width are 100 \( \mu \)m (green), 80 \( \mu \)m (black), 40 \( \mu \)m (red), 30 \( \mu \)m (blue) respectively. Design 5 (yellow) and 6 (pink) are structure B and C respectively.](image1)

![Figure 3: The deformation \( D_{xy} \) as a function of time for five different inlet velocities, \( v = 2 \) mm/s (yellow), 4 mm/s (green), 6 mm/s (blue), 8 mm/s (blue), 10 mm/s (red).](image2)

![Figure 4: The deformation \( D_{xy} \) as a function of time for five different liquid viscosities \( \eta \) (red), 1 mPa·s (red), 3 mPa·s (green), 5 mPa·s (black), 7 mPa·s (blue), 10 mPa·s (yellow).](image3)

![Figure 5: The deformation \( D_{xy} \) as a function of time for six different cell types, endothelial cells (red), fibroblasts (green), chondrocytes (black), chondrocyte nuclei (yellow), rat osteosarcoma cells (pink), bovine chondrocytes (blue).](image4)

Conclusion and future work
Substantial cell deformation can be obtained with use of the cross slot device. Currently, we are fabricating the cross slot designs to be used in future experiments of cell deformation.
