Abstract

We describe a method for proving non-termination of term rewriting systems that do not admit looping reductions. As certificates of non-termination, we employ regular (tree) automata.

1998 ACM Subject Classification D.1.1, D.3.1, F.4.1, F.4.2, I.1.1, I.1.3

Keywords and phrases non-termination, finite automata, regular languages

1 Introduction

We describe a method for proving non-termination of term rewriting systems that do not admit looping reductions, that is, reductions from a term \( t \) to a term \( C[t\sigma] \) containing a substitution instance of \( t \). For this purpose, we employ tree automata as certificates of non-termination. For proving non-termination of a term rewriting system \( R \), we search a tree automaton \( A \) whose language \( L(A) \) is not empty, weakly closed under rewriting and every term of the language contains a redex occurrence. We have fully automated the search for these certificates employing SAT-solvers.

All automata that we use as example in this paper have been found automatically; this concerns in particular fully automated proofs of non-termination for the following two rewrite systems.

\begin{itemize}
  \item \textbf{Example 1.} We consider the following string rewriting system:
    \[
    zL \rightarrow Lz \quad Rz \rightarrow zR \quad bL \rightarrow bR \quad Rb \rightarrow Lzb
    \]
    This rewrite system admits no reductions of the form \( s \rightarrow^{*} \ell sr \).
  \item \textbf{Example 2.} We consider the \( S \)-rule from combinatory logic:
    \[
    ap(ap(S, x), y), z \rightarrow ap(ap(x, z), ap(y, z))
    \]
    For the \( S \)-rule it is known that there are no reductions \( t \rightarrow^{*} C[t] \) for ground terms \( t \), see \textsuperscript{15}. For open terms \( t \) the existence of reductions \( t \rightarrow^{*} C[t\sigma] \) is open.
\end{itemize}

It turns out that the method can be fruitfully applied to obtain non-termination proofs of several string rewriting systems that have remained unsolved in the last full run of the termination competition.

Non-termination using Regular Languages

Related Work

Non-termination beyond loops has been investigated in [14] and [2]; we note that Example 2 cannot be handled by these techniques.

Here we prove non-looping non-termination on regular languages. The converse, local termination on regular languages, has been investigated in [3]. Regular (tree) automata have been fruitfully applied to a wide rage of properties of term rewriting systems: for proving termination [10, 8, 12], for infinitary normalization [4], for proving liveness [13], and for analysing reachability and deciding the existence of common reducts [9, 5].

2 Non-termination and Weakly Closed Languages

Definition 3. Let \( L \subseteq T(\Sigma, \emptyset) \) a language and \( R \) a TRS over \( \Sigma \). Then \( L \) is called:
- closed under rewriting if for every \( t \in L \) and \( s \) such that \( t \rightarrow s \), one has \( s \in L \), and
- weakly closed under rewriting if for every \( t \in L \) that is not in normal form, there exists \( s \in L \) such that \( t \rightarrow_{R} s \).

The following theorem describes the basic idea that we employ for proving non-termination.

Theorem 4. A term rewriting system \( R \) over \( \Sigma \) is non-terminating if and only if there exists a non-empty language \( L \subseteq T(\Sigma, \mathcal{X}) \) such that

(i) every \( t \in L \) contains a redex (that is, \( t \rightarrow s \) for some term \( s \)), and
(ii) \( L \) is weakly closed under rewriting.

A language fulfilling the properties of Theorem 4 is also called a recurrence set, see [1].

To automate this method, we need to restrict to a certain family of languages. In this paper, we consider regular tree languages. To guarantee that the language of a tree automaton is weakly closed under rewriting, we check that the language is not empty and that the automaton is a quasi-model (see Definition 13) for the rewrite system. The latter condition is actually too strict; it implies that the languages is not only weakly closed, but also closed under rewriting. In future, we plan to relieve this restriction.

3 Tree Automata

Definition 5. A (nondeterministic finite) tree automaton \( A \) over a signature \( \Sigma \) is a tuple \( A = \langle Q, \Sigma, F, \delta \rangle \) where

(i) \( Q \) is a finite set of states,
(ii) \( F \subseteq Q \) is a set of accepting states, and
(iii) \( \{\delta_f\}_{f \in \Sigma} \) is a family of transition relations such that for every \( f \in \Sigma \):

\[ \delta_f \subseteq Q^n \times Q \]

where \( n \) is the arity of \( f \).

In examples, we often write the transition relation \( \delta_f \) as \( \rightarrow_f \).
Whenever

Thus

In Example 12 we show that this automaton accepts the term

system

Definition 13.

▶

that is, all words that start with

terms

▶

Q

string rewriting systems as term rewriting systems by interpreting all symbols as unary and

adding a special constant $\varepsilon$ to denote the end of the word. Let $A_{LR} = \langle Q, \Sigma, F, \rightarrow \rangle$ where $Q = \{0, 1, 2, 3\}$, $\Sigma = \{b, L, R, 0, \varepsilon\}$, $F = \{3\}$ and

\[
\begin{array}{cccc}
\rightarrow_{\varepsilon} & 0 & 1 & 0 \rightarrow_b 1 \\
2 & \rightarrow_{\varepsilon} 2 & 2 & \rightarrow_b 3
\end{array}
\]

The transition relation for $\varepsilon$ can be thought of as defining the initial states (here 0) of a word automaton.

▶

Example 7. The following is a tree automaton for Example 2. Let $A_S = \langle Q, \Sigma, F, \rightarrow \rangle$ where $Q = \{0, 1, 2, 3, 4\}$, $\Sigma = \{ap, S\}$, $F = \{4\}$ and

\[
\begin{array}{cccc}
\rightarrow_{S} & 0 & (0, 0) & \rightarrow_{ap} 1 \\
2 & (0, 2) & \rightarrow_{ap} 2 & (0, 3) \\
4 & (1, 0) & \rightarrow_{ap} 2 & (1, 2)
\end{array}
\]

In Example 12 we show that this automaton accepts the term $SSS(SSS)(SSS(SSS))$.

▶

Example 9. We use the automaton $A_S$ from Example 2. Let $\alpha(x) = \{2\}$, then we have:

\[
\begin{array}{ccc}
[S, \alpha] = \{0\} & [ap(S, S), \alpha] = \{1\} & [ap(ap(S, S), S), \alpha] = \{2\} \\
[ap(x, x), \alpha] = \{3\} & [ap(ap(x, x), ap(x, x)), \alpha] = \{3, 4\}
\end{array}
\]

▶

Example 10. Let $A = \langle Q, \Sigma, F, \delta \rangle$ be a tree automaton over $\Sigma$. The language $L(A)$ accepted by $A$ is the set $L(A) = \{t \mid t \in T(\Sigma, \varnothing), [t]_A \cap F \neq \varnothing \}$ of ground terms.

▶

Example 11. The automaton in Example 6 accepts all words of the form $b z^* (L|R) z^* b$, that is, all words that start with $b$, end with $b$, contain one $L$ or $R$ and otherwise only $z$.

▶

Example 12. We continue Example 9

\[
\begin{array}{c}
[ap(ap(S, S), S)] = \{2\} \\
[ap(ap(S, S), S), ap(S, S), ap(S, S))] = \{3\}
\end{array}
\]

Thus $F \cap [SSS(SSS)(SSS(SSS))] = \{4\} \neq \varnothing$ and hence the term is accepted by the automaton.

4 Closure under Rewriting

▶

Definition 13. A tree automaton $A = \langle Q, \Sigma, F, \delta \rangle$ is a quasi-model for a term rewriting system $R$ over $\Sigma$ if $[\ell, \alpha]_A \subseteq [r, \alpha]_A$ for every $\ell \rightarrow r \in R$ and $\alpha : \mathcal{X} \rightarrow \mathcal{P}(Q)$.
4 Non-termination using Regular Languages

Actually, it suffices to check the property \([\ell, \alpha] \subseteq [r, \alpha]_A\) for assignments \(\alpha : X \to \mathcal{P}(Q)\) that map variables to singleton sets.

- **Lemma 14.** A tree automaton \(A = (Q, \Sigma, F, \delta)\) is a quasi-model for a term rewriting system \(R\) over \(\Sigma\) iff \([\ell, \alpha] \subseteq [r, \alpha]_A\) for every \(\ell \to r \in R\) and \(\alpha : X \to \{\{q\} \mid q \in Q\}\).

- **Example 15.** It is not difficult to check that the automaton \(A_{LR}\) from Example 6 is a quasi-model for rewrite system in Example 7.

- **Example 16.** We consider the automaton \(A_S\) from Example 7. We write \((a, b, c) \to d\) if \(d \in [\ell, \alpha]\) when \(\alpha(x) = \{a\}, \alpha(y) = \{b\}, \alpha(z) = \{c\}\). Then for \([\ell, \alpha]\) we have:

\[
(0, 0, 2) \to 1 \quad (2, 2, 3) \to 3 \quad (2, 3, 3) \to 3 \quad (3, 2, 3) \to 3 \quad (3, 3, 3) \to 3
\]

\[
(0, 0, 3) \to 1 \quad (2, 2, 3) \to 4 \quad (2, 3, 3) \to 4 \quad (3, 2, 3) \to 4 \quad (3, 3, 3) \to 4
\]

The interpretation \([r, \alpha]\) has all the above and additionally:

\[
(0, 2, 2) \to 3 \quad (1, 1, 0) \to 3 \quad (2, 2, 2) \to 3
\]

\[
(0, 2, 3) \to 3 \quad (2, 2, 2) \to 4
\]

\[
(0, 3, 3) \to 3
\]

As a consequence \(A_S\) is a quasi-model for the \(S\)-rule.

The following theorem is immediate:

- **Theorem 17.** Let \(A = (Q, \Sigma, F, \delta)\) be a tree automaton and \(R\) a term rewriting system over \(\Sigma\). If \(A\) is a quasi-model for \(R\) then the language of \(A\) is closed under rewriting.

5 Ensuring Redex Occurrences

Next, we want to guarantee that every term in the language \(\mathcal{L}(A)\) of an automaton \(A\) contains a redex with respect to the term rewriting system \(R\). For left-linear systems \(R\), this problem can be reduced to deciding the inclusion of regular languages.

Let \(R\) be a left-linear term rewriting system. Then the set of ground terms containing a redex is a regular tree language. A deterministic automaton \(B\) for this language can be constructed using the overlap-closure of subterms of left-hand sides, see further [6, 7].

- **Example 18.** The following tree automaton \(C = (Q, \Sigma, F, \to)\) accepts the language of ground terms that contain a redex occurrence with respect to the \(S\)-rule. Here \(Q = \{0, 1, 2, 3\}, \Sigma = \{ap, S\}, F = \{3\}\) and

\[
\begin{align*}
\to_S 0 & \quad (0, q) \to_{ap} 1 & \quad (1, q) \to_{ap} 2 & \quad (2, q) \to_{ap} 3 & \quad (3, q) \to_{ap} 3 & \quad (q, 3) \to_{ap} 3
\end{align*}
\]

for all \(q \in \{0, 1, 2\}\).

As a consequence the problem of checking whether every term in \(\mathcal{L}(A)\) contains a redex boils down to checking that \(\mathcal{L}(A) \subseteq \mathcal{L}(B)\). For non-deterministic \(A\) and deterministic \(B\), this property can be decided by constructing the product automaton and considering the reachable states.

- **Definition 19.** The product \(A \cdot B\) of tree automata \(A = (Q, \Sigma, F, \delta)\) and \(B = (Q', \Sigma, F', \delta')\) is the automaton \(C = (Q \times Q', \Sigma, \emptyset, \gamma)\) where for every \(f \in \Sigma\) of arity \(n\), we define the transition relation \(\gamma_f \subseteq (Q \times Q')^n \times (Q \times Q')\) by

\[
\langle (q_1, p_1), \ldots, (q_n, p_n) \rangle \gamma (q', p') \iff \langle q_1, \ldots, q_n \rangle \delta_f q' \land \langle p_1, \ldots, p_n \rangle \delta'_f p'\]
Definition 20. The set of reachable states of a tree automaton \( A = \langle Q, \Sigma, F, \delta \rangle \) is the smallest set \( S \subseteq Q \) such that \( q \in S \) whenever \( \langle q_1, \ldots, q_n \rangle \delta f q \) for some \( q_1, \ldots, q_n \in S \) and \( f \in \Sigma \) with arity \( n \).

The following theorem gives a method for checking \( L(A) \subseteq L(B) \) without the need for determinising \( A \) (only \( B \) needs to be deterministic).

Theorem 21. Let \( A = \langle Q, \Sigma, F, \delta \rangle \) and \( B = \langle Q', \Sigma, F', \delta' \rangle \) be tree automata such that \( B \) is deterministic. Let \( S \) be the set of reachable states of the product automaton \( A \cdot B \). Then \( L(A) \subseteq L(B) \) if and only if for all \( (q, p) \in S \) it holds that \( q \in F \implies p \in F' \).

Example 22. The reachable states of product automaton \( A \cdot C \) of the automata \( A \) from Example 7 and \( C \) from Example 18 are \((0, 0), (1, 1), (2, 2), (2, 1), (3, 3), (3, 2), (2, 3), (4, 3)\). The only state \( (q, q') \) such that \( q \) is accepting in \( A \) is \((4, 3)\) and \( 3 \) is an accepting state of \( C \). Thus the conditions of Theorem 21 are fulfilled and hence \( L(A) \subseteq L(C) \). Thus every term accepted by \( A \) contains a redex.

Future Work

We plan to investigate whether the method described in this paper can be fruitfully extended from regular automata to pushdown automata, that is, context-free languages. For this purpose, it is important that it is decidable whether a context-free language is a subset of a regular language (the language of terms containing left-linear redex occurrences). However, it remains to be investigated whether context-free certificates can be found efficiently.
