Document Version
Accepted manuscript including changes made at the peer-review stage

Please check the document version of this publication:

• A submitted manuscript is the author's version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.
• The final author version and the galley proof are versions of the publication after peer review.
• The final published version features the final layout of the paper including the volume, issue and page numbers.

Keywords: thin liquid films, dielectrophoresis, electrostatic surface charge

In high speed roll-to-roll coating processes, static electricity is a topic of concern [1] due to for example dust attraction and risk of spark generation. On the other hand, static charges can be employed to promote wetting in the deposition of coatings [2].

In our experiments, we deposited patterns of static charges by dragging an electrified water droplet in a predefined trajectory over a dielectric substrate. We performed two-dimensional characterization of the deposited charge distributions by scanning the substrate with a high-resolution electrostatic voltmeter.

After charge deposition, we applied a thin dielectric liquid film and quantified the deformation of the liquid film due to the electrical forces using interference microscopy. We studied the dielectrophoretic thin film deformation as a function of time and static charge density.

We also performed numerical simulations based on the lubrication approximation [4] and achieve good agreement with the experimental results. Numerically, we also investigated the effect of the width of the static charge distribution patterns and the initial film thickness.

Fig. 1: (a) Surface charge density distributions on a dielectric substrate generated by dragging water droplets that were kept at different voltages [3]. (b) Deformation of a thin dielectric liquid film on a polymer substrate with a non-homogeneous charge distribution (indicated by the red zone).

This work is part of the research programme ‘Contact Line Control During Wetting and Dewetting’, financially supported by foundation FOM and industrial partners ASML and Océ.
