Publisher’s PDF, also known as Version of Record (includes final page, issue and volume numbers)

Please check the document version of this publication:

• A submitted manuscript is the version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher’s website.
• The final author version and the galley proof are versions of the publication after peer review.
• The final published version features the final layout of the paper including the volume, issue and page numbers.

Riemann-Finsler Geometry and its Applications to Diffusion Magnetic Resonance Imaging

Luc Florack∗, Andrea Fuster ∗, and Tom Dela Haije ∗

Abstract—Riemannian geometry has become a popular mathematical framework for the analysis of diffusion tensor images (DTI) in diffusion weighted magnetic resonance imaging (DWMRI). If one declines from the a priori constraint to model local anisotropic diffusion in terms of a 6-degrees-of-freedom rank-2 DTI tensor, then Riemann-Finsler geometry appears to be the natural extension. As such it provides an interesting alternative to the Riemannian rationale in the context of the various high angular resolution diffusion imaging (HARDI) schemes proposed in the literature. The main advantages of the proposed Riemann-Finsler paradigm are its manifest incorporation of the DTI model as a limiting case via a “correspondence principle” (operationalized in terms of a vanishing Cartan tensor), and its direct connection to the physics of DWMRI expressed by the (appropriately generalized) Stejskal-Tanner equation and Bloch-Torrey equations furnished with a diffusion term.

I. INTRODUCTION

Riemann-Finsler geometry, already hinted upon by Riemann in his “Habilitation” [1], is a generalization of Riemannian geometry. The latter has found important applications in Maxwell theory and Einstein’s theory of general relativity, contributing greatly to its popularity. The general case was taken up by Finsler [2], Cartan [3] (referring to it as “Finsler geometry”), and others [4], [5], [6].

Despite its great potential, Riemann-Finsler geometry has not become nearly as popular as its Riemannian limit. To some extent this may be explained by its rather mind-boggling technicalities and heavy computational demands (due to the introduction of an additional vectorial dimension extending the base manifold). Another key factor is the still open challenge to find important “natural” application areas for it, and to show its added value in these areas. We conjecture that DWMRI could be one such application area. This imaging modality plays an important role in the unravelment of the human brain connectome, among others.

II. THEORY

The pivot of Riemann-Finsler geometry is a generalised notion of length of a spatial curve $C$ (“Hilbert’s invariant integral” [4]):

$$\mathcal{L}(C) = \int_C F(x, dx).$$

The so-called Finsler function $F(x,\xi)$ is positive definite for $\xi \neq 0$, and homogeneous of degree one in $\xi$, i.e. $F(x,\lambda\xi) = |\lambda| F(x,\xi)$ for all $\lambda$. In addition, the Riemann-Finsler metric tensor, defined as

$$g_{ij}(x,\xi) = \frac{1}{2} \frac{\partial^2 F^2(x,\xi)}{\partial \xi^i \partial \xi^j},$$

is positive definite. It is easy to see that (applying summation convention)

$$F(x,\xi) = \sqrt{g_{ij}(x,\xi)\xi^i\xi^j}.$$  

Riemann’s “quadratic restriction” pertains to the “mildly anisotropic” case $g_{ij}(x,\xi) = g_{ij}(x)$.

The non-Riemannian nature of the Riemann-Finsler manifold is most concisely expressed in terms of the so-called Cartan tensor:

$$C_{ijk}(x,\xi) = \frac{1}{4} \frac{\partial^3 F^2(x,\xi)}{\partial \xi^i \partial \xi^j \partial \xi^k}.$$  

A dual, or Hamiltonian formulation rests upon the identity

$$g^{ij}(x,\xi) g_{ij}(x,\xi) = \delta,$$

in which the first factor on the l.h.s. defines the dual Riemann-Finsler metric tensor, and in which it is understood that

$$g_{ij}(x,\xi) g^{ij}(x,\xi) = \delta$$
or, equivalently, $$\xi^i g_{ij}(x,y)\xi_j.$$  

We stipulate that the dual Finsler function, $H(x, y) = F(x, \xi)$, governs signal attenuation in DWMRI if, as with DTI, one relies on the Stejskal-Tanner (mono-exponential decay, Gaussian diffusion) and Bloch-Torrey equations with diffusion term [7], [8], [9], viz.

$$S(x,y) = S(x,0) \exp \left(-\tau H^2(x,y)\right).$$

Here $\tau$ denotes a time constant related to the time $\Delta$ between a pair of balanced diffusion-sensitizing gradients $G$, and pulse duration $\delta$ (in Stejskal-Tanner’s scheme we have $\tau = \Delta - \delta/3$),

$$H(x, y) = \sqrt{g_{ij}(x, y)\xi^i\xi^j},$$

with “momentum” $g_{ij}(x, y)\xi^i\xi^j$, given in terms of $\delta$, $G$, and hydrogen gyromagnetic ratio $\gamma$. The DTI rationale [10], [11] is based on the (strong) simplification that the $(y$-independent) diffusion tensor image $D(x)$ can be identified with $g_{ij}(x, y)$.

Further details can be found in a forthcoming publication [12].
