UNIVERSALITY FOR FIRST PASSAGE PERCOLATION ON SPARSE RANDOM GRAPHS

SHANKAR BHAMIDI\textsuperscript{1}, REMCO VAN DER HOFSTAD\textsuperscript{2}, AND GERARD HOOGHIEMSTRA\textsuperscript{3}

Abstract. We consider first passage percolation on the configuration model with \( n \) vertices, and general independent and identically distributed edge weights assumed to have a density. Assuming that the degree distribution satisfies a uniform \( X^2 \log X \)-condition, we analyze the asymptotic distribution for the minimal weight path between a pair of typical vertices, as well the number of edges on this path namely the hopcount.

The hopcount satisfies a central limit theorem (CLT). Furthermore, writing \( L_n \) for the weight of this optimal path, then we shown that \( L_n - (\log n)/\alpha_n \) converges to a limiting random variable, for some sequence \( \alpha_n \). This sequence \( \alpha_n \) and the norming constants for the CLT are expressible in terms of the parameters of an associated continuous-time branching process that describes the growth of neighborhoods around a uniformly chosen vertex in the random graph. The limit of \( L_n - (\log n)/\alpha_n \) equals the sum of the logarithm of the product of two independent martingale limits, and a Gumbel random variable. Till date, for sparse random graph models, such results have been shown only for the special case where the edge weights have an exponential distribution, wherein the Markov property of this distribution plays a crucial role in the technical analysis of the problem.

The proofs in the paper rely on a refined coupling between shortest path trees and continuous-time branching processes, and on a Poisson point process limit for the potential closing edges of shortest-weight paths between the source and destination.

1. INTRODUCTION AND RESULTS

1.1. Motivation. First passage percolation (FPP) is an important topic in modern probability theory, motivated by questions in a number of fields including disordered systems in statistical physics, where it arises as a building block in the analysis of complicated interacting particle systems such as the contact process, branching random walk and various epidemic models.

Let us start by describing the basic model. Let \( G \) be a connected graph on \( n \) vertices. Assign independent and identically distributed (i.i.d.) random edge weights or lengths to the edges of the graph. These random edge weights generate geodesics on the graph. Think of the graph as a disordered random system carrying flow between pairs of vertices in the graph via shortest paths between them. Choose two vertices in the graph uniformly at random amongst the \( n \) vertices. We will call these two vertices “typical” vertices. Two functionals of interest are the minimal weight \( L_n \) of a path between the two vertices and the number of edges \( H_n \) on the minimal path, often referred to as the hopcount. We assume that the common distribution of the edge weights is continuous, so that the optimal paths are a.s. unique and one can talk about objects such as the number of edges in the optimal path.

This model has been studied intensively, largely in the context of the integer lattice \([-N, N]^d\) (see e.g. [19, 22, 29, 38]). For the power of this model to analyze more complicated interacting

particle systems, see [32] and [16] and the references therein. In the modern context, FPP problems take on an added significance. Many real-world networks (such as the Internet at the router level or various road and rail networks) are entrusted with carrying flow between various parts of the network. These networks have both a graph theoretic structure as well as weights on edges, representing for example congestion. In the applied setting, understanding properties of both the hopcount and the minimal weight are crucial, since whilst routing is done via least weight paths, the actual time delay experienced by users scales like the hopcount (the number of “hops” a message has to perform in getting from the source to the destination). Simulation-based studies (see e.g. [13]) suggest that random edge weights have a marked effect on the geometry of the network. This has been rigorously established in various works [3, 8–10], in the specific case of edge weights.

In this paper, we study the behavior of the hopcount and minimal weight in the setting of random graphs with finite variance degrees and general continuous edge weights. Since in many applications, the distribution of edge weights is unknown, the assumption of general weights is highly relevant. From a mathematical point of view, working with general instead of exponential edge weights implies that our exploration process is non-Markovian. This is the first paper that studies first passage percolation on random graph models in this general setting. In a forthcoming paper [7] we will show that, due to the flexible choice of degree distribution, our results carry over to various other random graph models, including rank-1 inhomogeneous random graphs as introduced in [12].

**Organization of this section.** We start by introducing the configuration model in Section 1.2, where we also state our main result, Theorem 1.2. In Section 1.3, we discuss a continuous-time branching process approximation, which is necessary to identify the limiting variables in Theorem 1.2; this identification is done in Theorem 1.3. In Section 1.4, we study some examples that allow us to relate our results to existing results in the literature. We close with Section 1.5 where we present a discussion of our results and pose some open problems.

Throughout this paper, we make use of the following standard notation. We let $\overset{a.s.}\to$ denote convergence almost surely, $\overset{L^1}\to$ denote convergence in mean, $\overset{d}\to$ denote convergence in distribution, and $\overset{p}\to$ convergence in probability. For a sequence of random variables $(X_n)_{n \geq 1}$, we write $X_n = O_p(b_n)$ when $|X_n|/b_n$ is a tight sequence of random variables, and $X_n = o_p(b_n)$ when $|X_n|/b_n \overset{p}\to 0$, as $n \to \infty$. We write $D \sim F$ to denote that the random variable $D$ has distribution function $F$. For non-negative functions $n \to f(n), n \to g(n)$, we write $f(n) = O(g(n))$ when $f(n)/g(n)$ is uniformly bounded, and $f(n) = o(g(n))$ when $\lim_{n \to \infty} f(n)/g(n) = 0$. Furthermore, we write $f(n) = \Theta(g(n))$ if $f(n) = O(g(n))$ and $g(n) = O(f(n))$. Finally, we say that a sequence of events $(E_n)_{n \geq 1}$ occurs with high probability (whp) when $\mathbb{P}(E_n) \to 1$.

**1.2. Configuration model and main result.** The configuration model (CM) is a random graph with vertex set $[n] := \{1, 2, \ldots, n\}$ and with prescribed degrees. Let $d = (d_1, d_2, \ldots, d_n)$ be a given degree sequence, i.e., a sequence of $n$ positive integers with total degree

$$\ell_n = \sum_{i \in [n]} d_i,$$  \hspace{1cm} (1.1)

assumed to be even. The CM on $n$ vertices with degree sequence $d$ is constructed as follows: start with $n$ vertices and $d_i$ half-edges adjacent to vertex $i \in [n]$. Randomly choose pairs of half-edges and match the chosen pairs together to form edges. Although self-loops may occur, these become rare as $n \to \infty$ (see e.g. [11, 25]). We denote the resulting graph on $[n]$ by $\text{CM}_n(d)$, with corresponding edge set $\mathcal{E}_n$.

**Regularity of vertex degrees.** Let us now describe our regularity assumptions on the degree sequence $d$ as $n \to \infty$. We denote the degree of a uniformly chosen vertex $V$ in $[n]$ by $D_n = d_V$. 

The random variable $D_n$ has distribution function $F_n$ given by

$$F_n(x) = \frac{1}{n} \sum_{j \in [n]} \mathbb{1}_{\{d_j \leq x\}}, \quad (1.2)$$

where $\mathbb{1}_A$ denotes the indicator of the event $A$. We write $\log(x)_+ = \log(x)$ for $x \geq 1$ and $\log(x)_+ = 0$ for $x \leq 1$. Then our regularity condition is as follows:

**Condition 1.1 (Regularity conditions for vertex degrees).**

(a) **Weak convergence of vertex degree.**

There exists a cumulative distribution function $F$ of a discrete random variable $D$, taking values in $\mathbb{N}$ such that

$$\lim_{n \to \infty} F_n(x) = F(x), \quad (1.3)$$

for any continuity point $x$ of $F$; i.e., $D_n \xrightarrow{d} D$.

(b) **Convergence of second moment.**

$$\lim_{n \to \infty} \mathbb{E}[D_n^2] = \lim_{n \to \infty} \frac{1}{n} \sum_{j \in [n]} d_j^2 = \mathbb{E}[D^2], \quad (1.4)$$

where $D_n$ and $D$ have distribution functions $F_n$ and $F$, respectively, and we assume that

$$\nu = \mathbb{E}[D(D - 1)]/\mathbb{E}[D] > 1. \quad (1.5)$$

(c) **Uniform $X^2 \log X$-condition.** For every $K_n \to \infty$,

$$\lim_{n \to \infty} \mathbb{E}[D_n^2 \log (D_n/K_n)_+] = \lim_{n \to \infty} \frac{1}{n} \sum_{j \in [n]} d_j^2 \log \left(\frac{d_j}{K_n}\right)_+ = 0. \quad (1.6)$$

By Condition 1.1(c), the random degree $D_n$ satisfies a uniform $X^2 \log X$-condition if and only if $D_n$ satisfies a uniform $X^2 \log X$-condition. As explained in more detail in Section 1.3 below, $D^*_n$ is closely related to a branching-process approximation of neighborhoods of a uniform vertex, and Condition 1.1(c) implies that this branching process satisfies a uniform $X \log X$ condition. By uniform integrability, Condition 1.1(c) follows from the assumption that $\lim_{n \to \infty} \mathbb{E}[D_n^2 \log (D_n)_+] = \mathbb{E}[D^2 \log (D)_+]$.

Note that that Conditions 1.1(a) and (c) imply that $\mathbb{E}[D_i^2] \to \mathbb{E}[D^2]$, $i = 1, 2$. When the degrees are random themselves, then the distribution function $F_n$ as well as the left-hand side of (1.4) and (1.6), are random and we assume that the convergence in (1.3), (1.4) and (1.6) to the respective (deterministic) right-hand sides holds in probability. Thus, in this case, we require that, with $\mathbb{E}_n[D_i^2] = \frac{1}{n} \sum_{j \in [n]} d_j^2$ (which is now a random variable) and for every $\varepsilon > 0$ and $i \in \{1, 2\}$,

$$\lim_{n \to \infty} \mathbb{P}(|F_n(x) - F(x)| \geq \varepsilon) = 0, \quad \forall x \in \mathbb{R}, \quad \lim_{n \to \infty} \mathbb{P}(|\mathbb{E}_n[D_i^2] - \mathbb{E}[D^2]| \geq \varepsilon) = 0. \quad (1.8)$$

A similar condition replaces (1.6).

Condition (1.5) is equivalent to the existence of a giant component in $\text{CM}_n(d)$, see e.g. [27, 34, 35]. Let $F$ be a distribution function of a random variable $D$, satisfying (1.5) and $\mathbb{E}[D^2 \log (D)_+] < \infty$. We give two canonical examples in which Condition 1.1 holds. The first is when there are precisely $n_k = [nF(k)] - [nF(k - 1)]$ vertices having degree $k \geq 1$. The second is when $(d_i)_{i \in [n]}$ is an i.i.d. sequence of random variables with distribution function $F$ (in the case that $\sum_{i \in [n]} d_i$ is odd, we increase $d_n$ by 1, this does not affect the results).
**Edge weights and shortest paths.** Once the graph has been constructed, we attach an edge weight $\xi_v$ to every edge $e$, where $(\xi_v)_{v \in V}$ are i.i.d. continuous random variables with density $f_\xi: [0, \infty) \to [0, \infty)$ and corresponding distribution function $F_\xi$. Pick two vertices $U_1$ and $U_2$ at random from $[n]$ and let $\Gamma_{12}$ denote the set of all paths in $CM_n(d)$ between these two vertices. For any path $\pi \in \Gamma_{12}$, the weight of the path is defined as
\[ \sum_{e \in \pi} \xi_e. \]  
Let
\[ L_n = \min_{\pi \in \Gamma_{12}} \sum_{e \in \pi} \xi_e, \]  
denote the weight of the optimal (i.e., minimal weight) path between the $U_1$ and $U_2$ and let $H_n$ denote the number of edges or the hopcount of this path. If the two vertices are in different components of the graph, then we let $L_n, H_n = \infty$. We are ready to state our main result. Due to the complexity of the various constants and limiting random variables arising in the theorem, we defer their complete description to the next section.

**Theorem 1.2 (Joint convergence of hopcount and weight).** Consider the configuration model $CM_n(d)$ with degrees $d$ satisfying Condition 1.1, and with i.i.d. edge weights distributed according to the continuous distribution $F_\xi$. Then, there exist constants $\alpha, \beta, \gamma \in (0, \infty)$ and $\alpha_n, \gamma_n$ with $\alpha_n \to \alpha, \gamma_n \to \gamma$, such that the hopcount $H_n$ and weight $L_n$ of the optimal path between two uniformly chosen vertices, conditioned on being connected, satisfy
\[ \left( \frac{H_n - \gamma_n \log n}{\sqrt{\beta \log n}}, \frac{L_n - 1}{\alpha_n \log n} \right) \xrightarrow{d} (Z, Q), \]  
as $n \to \infty$, where $Z$ and $Q$ are independent and $Z$ has a standard normal distribution, while $Q$ has a continuous distribution.

This is the first time that FPP on sparse random graphs with general edge weights has been studied; for the particular case where the edge weights have an exponential distribution see e.g. [9].

In Remark 1.4 below, we will state conditions that imply that we can replace $\alpha_n$ and $\gamma_n$ by their limits $\alpha$ and $\gamma$, respectively. Theorem 1.2 shows a remarkable degree of universality. For $CM_n(d)$ satisfying Condition 1.1, the hopcount always satisfies a central limit theorem with mean and variance proportional to $\log n$. Also, the weight of the shortest weight path between two uniformly chosen vertices always is of order $\log n$, and the fluctuations around $\log n/\alpha_n$ converge in distribution. We will see that even the limit $Q$ has a large degree of universality. For this, as well as to define the parameters $\alpha, \alpha_n, \beta, \gamma, \gamma_n$, we first need to describe a continuous-time branching process approximation.

1.3. **Continuous-time branching processes.** In this section, we define the limiting continuous-time branching process (CTBP) that describes the neighborhood structure of first passage percolation on $CM_n(d)$. Define the size-biased distribution $F^*$ of the random variable $D$ with distribution function $F$ by
\[ F^*(x) = \frac{E[D \cdot 1_{\{D \leq x\}}]}{E[D]}, \quad x \in \mathbb{R}. \]  
When Condition 1.1(a)-(b) holds, the function $F^*$ is the weak limit as $n \to \infty$ of $F_n^*$ in (1.7). Now let $(BP^*_t(t))_{t \geq 0}$ denote the following CTBP: (a) At time $t = 0$, we start with one individual which we refer to as the original ancestor or the root of the branching process.

(b) Each individual $v$ in the branching process lives for a random amount of time which has distribution $F_\xi$, i.e., the edge weight distribution, and then dies. At the time of death the individual gives birth to $D^* - 1$ children, where $D^* \sim F^*$. Lifetimes and number of offspring across individuals are independent.

Note that in the above construction, by Condition 1.1(b), if we let $X_v = D^* - 1$ be the number of children of an individual, then the expected number of children satisfies
\[ E[X_v] = E[D^* - 1] = \nu > 1. \]  
(1.13)
Further, by Condition 1.1(c), for $D^* \sim F^*$,
\[ \mathbb{E}[D^* \log (D^*)] < \infty. \] (1.14)

The CTBP defined above is a standard Bellman-Harris process, with lifetime distribution $F_\xi$ and offspring distributed as $D^* - 1$ [4, 20, 23]. The Malthusian parameter $\alpha$ of the branching process $\text{BP}^*$ is the unique solution of the equation
\[ \hat{\mu}(\alpha) = \nu \int_0^\infty e^{-\alpha t} dF_\xi(t) = 1. \] (1.15)

Since $\nu > 1$, we obtain that $\alpha \in (0, \infty)$. We also let $\alpha_n$ be the solution to (1.15) with $\nu$ replaced by
\[ \nu_n = \mathbb{E}[D_n(D_n - 1)]/\mathbb{E}[D_n]. \] (1.16)

Clearly, $\alpha_n \to \alpha$ when Condition 1.1 holds, and further $|\alpha_n - \alpha| = O(|\nu_n - \nu|)$.

Standard theory (see e.g., [4, 20, 23]) implies that under our assumptions on the model, namely (1.13) and (1.14), there exists a random variable $\mathcal{W}^*$ such that
\[ e^{-\alpha t} \mathbb{P}^*([\text{BP}(t)]) \xrightarrow{a.s.} \mathcal{W}^*. \] (1.17)

Here the limiting random variable $\mathcal{W}^*$ satisfies $\mathcal{W}^* > 0$ a.s. on the event of non-extinction of the branching process and is zero otherwise. Thus $\alpha$ measures the true rate of exponential growth of the branching process.

By (1.15), we can define the cumulative distribution function $\bar{F}_\xi$, often referred to as the stable-age distribution, as
\[ \bar{F}_\xi(x) = \nu \int_0^x e^{-\alpha y} dF_\xi(y). \] (1.18)

Let $\bar{\nu}$ be the mean and $\bar{\sigma}^2$ the variance of $\bar{F}_\xi$, i.e.,
\[ \bar{\nu} = \nu \int_0^\infty xe^{-\alpha x} dF_\xi(x), \quad \bar{\sigma}^2 = \nu \int_0^\infty (x - \bar{\nu})^2 e^{-\alpha x} dF_\xi(x). \] (1.19)

Then $\bar{\nu}, \bar{\sigma}^2 \in (0, \infty)$, since $\alpha > 0$. We also define $\bar{F}_{n,\xi}$ to be the distribution function $\bar{F}_\xi$ in (1.18) with $\nu$ and $\alpha$ replaced by $\nu_n$ and $\alpha_n$, and we let $\bar{\nu}_n$ and $\bar{\sigma}_n^2$ be the corresponding mean and variance.

We need a small variation of the above standard CTBP, where the root of the branching process dies immediately giving birth to a $D$ number of children where $D$ has distribution $F$, the original (i.e., non size-biased) degree distribution as in Condition 1.1(a). The details for every other individual in this branching process remain unchanged from the original description, namely each individual survives for a random amount of time with distribution $F_\xi$ giving rise to a $D^* - 1$ number of children where $D^* \sim F^*$, the size-biased distribution function $F^*$ as in (1.12). Writing $|\text{BP}(t)|$ for the number of alive individuals at time $t$, it is easy to see here as well that
\[ e^{-\alpha t} |\text{BP}(t)| \xrightarrow{a.s.} \mathcal{W}. \] (1.20)

Further, conditionally on $D = k$,
\[ \tilde{\mathcal{W}} \overset{d}{=} \tilde{\mathcal{W}}^{*,(1)} + \cdots + \tilde{\mathcal{W}}^{*,(k)}, \]
where $D \sim F$, and $\tilde{\mathcal{W}}^{*,(i)}$ are i.i.d. with the distribution of the limiting random variable in (1.17).

Let $\mathcal{W}$ denote a random variable distributed as $\tilde{\mathcal{W}}$ conditioned to be positive, i.e., for every $x \geq 0$,
\[ \mathbb{P}(\mathcal{W} \leq x) = \mathbb{P}(\tilde{\mathcal{W}} \leq x \mid \tilde{\mathcal{W}} > 0). \] (1.21)

To simplify notation in the sequel, we will use $(\text{BP}(t))_{t \geq 0}$ to denote a CTBP with the root having offspring either one (as for the standard CTBP), $D$ or $D^* - 1$. It will be clear from the context which setting we are in.

We are now in a position to identify the limiting random variable $Q$ as well as the parameters $\alpha, \beta, \gamma, \alpha_n, \gamma_n$: ...
Theorem 1.3 (Identification of the limiting variables). The parameters $\alpha, \alpha_n, \beta, \gamma_n, \gamma$ in Theorem 1.2 satisfy that $\alpha$ is the Malthusian rate of growth defined in (1.15) and $\alpha_n$ is the solution to (1.15) with $\nu_n$ replacing $\nu$, while

$$\gamma = \frac{1}{\nu^2}, \quad \gamma_n = \frac{1}{\alpha_n\nu_n}, \quad \beta = \frac{\sigma^2}{\nu^2\alpha_n}. \quad (1.22)$$

Further, $Q$ can be identified as

$$Q = \frac{1}{\alpha} \left( -\log W^{(1)} - \log W^{(2)} - \Lambda + c \right), \quad (1.23)$$

where $\mathbb{P}(\Lambda \leq x) = e^{-e^{-x}}$ (so that $\Lambda$ is a standard Gumbel random variable). $W^{(1)}, W^{(2)}$ are two independent copies of the variable $W$ in (1.21), also independent from $\Lambda$, and $c$ is the constant

$$c = \log(\mathbb{E}[D]/(\nu - 1)^2/(\nu\alpha)). \quad (1.24)$$

Remark 1.4 (Asymptotic mean). In (1.11), we can replace $\alpha_n$ and $\gamma_n$ by their limits $\alpha$ and $\gamma$ precisely when $\gamma_n = \gamma + o(1/\sqrt{\log n})$ and $\alpha_n = \alpha + o(1/\log n)$. Since $|\alpha_n - \alpha| = O(|\nu_n - \nu|)$, $|\nu_n - \nu| = O(|\nu_n - \nu|)$, these conditions are equivalent to $\nu_n = \nu + o(1/\sqrt{\log n})$ and $\nu_n = \nu + o(1/\log n)$, respectively.

Theorem 1.3 implies that also the random variable $Q$ is remarkably universal, in the sense that it always involves two independent martingale limit variables corresponding to the branching processes, and a Gumbel distribution.

Let $L_n(i)$ denote the weight of the $i$th shortest path, so that $L_n = L_n(1)$, and let $H_n(i)$ denote its length. Further let $H_n(i)$ and $\bar{L}_n(i)$ denote the re-centered and normalized quantities as in Theorem 1.2. The same proof for the optimal path easily extends to prove asymptotic results for the joint distribution of the weights and hopcount of these ranked paths. To keep the study to a manageable length, we shall skip a proof of this easy extension.

Theorem 1.5 (Multiple paths). Under the conditions of Theorem 1.2, for every $m \geq 1$,

$$((\bar{H}_n(i), \bar{L}_n(i)))_{i \in [m]} \xrightarrow{d} ((Z_i, Q_i))_{i \in [m]}, \quad (1.25)$$

as $n \to \infty$, where for $i \in [m]$, $Z_i$ and $Q_i$ are independent and $Z_i$ has a standard normal distribution, while

$$Q_i = \frac{1}{\alpha} \left( -\log W^{(1)} - \log W^{(2)} - \Lambda_i + c \right), \quad (1.26)$$

where $(\Lambda_i)_{i \in [m]}$ are the ordered (minimal) points of an inhomogeneous Poisson point process with intensity $\lambda(t) = e^t$.

1.4. Examples. We treat some examples of edge-weight distributions that have appeared in the literature and have been treated via distribution-specific techniques.

(i) We start with exponential edge weights [3, 8–10]. In this case, it is immediate from (1.15) and (1.18) that

$$\alpha = \nu - 1, \quad \bar{\nu} = \bar{\sigma} = \frac{1}{\nu},$$

hence Theorems 1.2-1.3 show that $H_n$ converges to a normal distribution, with asymptotic mean and asymptotic variance both equal to $\frac{\nu}{\nu - 1} \log n$. Furthermore, Theorem 1.2 induces the convergence of the minimal weight in [9, 10]. Observe that the random variable $M$, which appears in [9, (C.19)], is equal to $-\Lambda$. In [10], the special case of the Erdős-Rényi random graph with exponential edge weights was tackled. There is a small error in the expression of the limiting random variable in [10, (4.16)].

(ii) By studying weights of the form $\xi_e = 1 + E_e/k$, where $(E_e)$ are i.i.d. exponentials with mean 1, and consecutively sending $k \to \infty$, one would expect to obtain results which are close to limiting results on the graph distance between a pair of uniformly chosen vertices in $[n]$, conditioned to be connected. Indeed, the results match up nicely with those in [17] for the Norros-Reittu model and [21] for the CM. For the sake of brevity we leave the derivation to the reader.
(iii) As a third example one can consider the CM with fixed degrees \( r \), and where each edge is given an edge weight \( E^s, s > 0 \), where \( E \sim \text{Exp}(1) \), a variant of the weak disorder models in statistical physics [13]. One can formally consider the case \( r = n - 1 \), although this does not satisfy the conditions of our theorem. Here the CM with fixed degrees \( n - 1 \) resembles a complete graph on \( [n] \) and the results match up nicely with those in [6], namely, a central limit theorem for \( H_n \) with asymptotic mean \( s \log n \) and asymptotic variance \( s^2 \log n \), while \( n^s[L_n - \frac{1}{2} \log n] \) converges in distribution, where \( \lambda = \Gamma(1 + 1/s)^s \). We refer to [6] for the derivation of these parameters.

1.5. Discussion. In this section, we give a brief discussion of our results, possible extensions and open problems.

(a) **Universality.** Our results are universal in the sense that, as Theorems 1.2-1.3 demonstrate, the CLT for the hopcount depends only on the first two moments of the size-biased offspring distribution and on the edge-weight distribution, but not on any other property of the network model. Further, the form of the limit random variable has a universal form in terms of the martingale limits of branching processes and a Gumbel random variable.

(b) **Infinite-variance configuration model.** In [9], we have investigated the CM with exponential edge weights, but with i.i.d. degrees with \( \mathbb{P}(D \geq x) \approx cx^{-(\tau-1)} \) and \( \tau \in (2, 3) \), so that \( \mathbb{E}[D^2] = \infty \). In this case, the result for \( L_n \) is markedly different, in the sense that \( L_n \) converges in distribution without re-centering. Further, \( H_n \) satisfies a central limit with asymptotic mean and variance equal to a multiple of \( \log n \). It would be of interest to investigate whether \( H_n \) always satisfies a central limit theorem, and, if so, whether the order of magnitude of its variance is always equal to that of its mean.

(c) **The \( X \log X \)-condition.** In Condition 1.1(c), we assume that the degrees satisfy a second moment condition with an additional logarithmic factor. This is equivalent to the CTBP satisfying an \( X \log X \)-condition (uniformly in the size \( n \) of the graph). It would be of interest to investigate what happens when this condition fails.

(d) **Flooding and diameter.** In [3], the flooding time and diameter, i.e., \( \max_{j \in [n]}: L_n(U_1,j) < \infty L_n(U_1,j) \), respectively \( \max_{i,j \in [n]}: L_n(i,j) < \infty L_n(i,j) \), where \( L_n(i,j) \) is the minimal weight between the vertices \( i \) and \( j \), is investigated in the context of the CM with exponential edge weights. It would be of interest to investigate the flooding time for general edge weights.

(e) **Superconcentration and chaos.** Analogous to various problems in statistical physics such as random polymers or FPP on the lattice, our results suggest that the FPP optimal path problem is chaotic. This means that there exists \( \varepsilon_n \to 0 \) such that refreshing a fraction \( \varepsilon_n \) of the edge weights with new random variables with the same distribution would entirely change the actual optimal path, in the sense that the new optimal path would be “almost” disjoint of the original optimal path, see e.g. [14]. Such questions have also arisen in computer science wherein one is interested in judging the “importance” and fair price of various edges in the optimal path; if an edge being deleted causes a large change in the cost of the new optimal path, then that edge is deemed very valuable. These form the basis of various “truth and auction mechanisms” in computer science (see e.g. [5,18,33]).

(f) **Pandemics, gossip and other models of diffusion.** First passage percolation models as well as models using FPP as a building block have started to play an increasingly central role in the applied probability community in describing the flow of materials, ranging from viral epidemics [15], gossip algorithms [2] and more general finite Markov interchange processes [1]. Models with more general edge weight distributions have also arisen in understanding the flow of information and reconstruction of such information networks in sociology and computer science, see e.g. [30,31] for examples in this vast field.

**Organization of this paper.** In Section 2, we describe the coupling between the first-passage percolation neighborhoods in \( \text{CM}_n(d) \) and a CTBP. In Section 3, we state our main technical result that describes a Poisson process limit for the occurrence of short paths between \( U_1 \) and \( U_2 \) which then proves our main theorem. In Section 4, we extend results for CTBPs, as proved
in [20,23,37], to the case of infinite-variance offspring distributions, using truncation. In Section 5, we prove bounds on our coupling. In Section 6, we give a novel proof of the asymptotics for the number of alive individuals in a CTBP in an given generation and with a given residual lifetime. This proof is tailored to deal with CTBPs observed till some time $t$ that have an offspring distribution that depends on $n$ where $n \to \infty$ and $t = t_n \to \infty$ simultaneously. In Section 7, we prove our main technical result on the Poisson process limit.

2. Coupling

In this section, we describe a coupling between FPP on $\text{CM}_n(d)$ and continuous-time branching processes. We start with an informal description.

2.1. Informal description of shortest weight trees. The model $\text{CM}_n(d)$ with edge set $E_n$ together with i.i.d. lengths (also referred to as weights) $(\xi_e)_{e \in E_n}$ on the edges, was introduced in Section 1.2. Here $\xi_e \sim F_\xi$, with density $f_\xi$. Our ultimate goal is to calculate the limit distribution of the hopcount $H_n$ and weight $L_n$ of the shortest path between a uniformly chosen pair of connected vertices $U_1$ and $U_2$, when Condition 1.1 is satisfied.

To obtain a proper understanding of the shortest path between two vertices, we imagine a liquid that percolates through the edges of the CM at rate one. We start percolating the liquid simultaneously from both vertices $U_1$ and $U_2$ and we interpret the edge weight $\xi_e$ on edge $e$ as the distance between the two vertices incident to $e$. For any $t \geq 0$, the set of half-edges that are currently being wetted by the liquid, as well as the residual time to completely wet them, starting from $U_i$ will be informally denoted as the shortest weight tree $\text{SWT}^{(i)}$, $i = 1, 2$. A precise definition of these SWT’s will be given in the next section. When the liquid has reached two vertices that are incident to a connecting edge between the two SWT’s, then a possible shortest path has been found. Since at that moment the connecting edge has not yet been filled, we can not be sure whether the given path between $U_1$ and $U_2$ is indeed the shortest one. Hence we have to find all connecting edges between the two SWT’s and take the minimum of all these path weights to determine $L_n$ and $H_n$.

In the mathematical description in the next section, we build the CM simultaneously with the liquid percolating through the edges. Since we will construct the process sequentially, it is easier to index the sequence of new edge-weights added to the system as $(\xi_j)_{j \geq 1}$. The half-edges emanating from the wetted vertices are called the alive half-edges $\text{AH}(t)$ at time $t$. During the building process, we form two SWT’s consisting of ‘alive’ half-edges and vertices attached to $U_i$, for $i = 1, 2$. In order to perform the building process properly, we put the i.i.d. weights $(\xi_j)_{j \geq 1}$ on the half-edges instead of on the edges. Technically one has to be extremely careful in constructing the process in this fashion. Imagine a situation where the liquid reaches both $a$ and $b$ for some edge $e$ formed by merging the half-edges $e = (a,b)$. Assigning independent half-edge weights $\xi_a$ and $\xi_0$ is then not the same as first passage percolation. Instead we put the weight on the half-edge that is found first by the liquid. We initiate the construction by putting weights $\xi_1, \ldots, \xi_{d_{U_1}}$ on the half-edges incident to $U_1$ and weights $\xi_{d_{U_1}+1}, \ldots, \xi_{d_{U_1}+d_{U_2}}$ on the half-edges incident to $U_2$. Of course, this creates a problem when these half-edges are paired to one another, which we have to take into account properly.

We construct a sequence of epoch times $(T_k)_{k \geq 0}$ that track when a decision has to be made. Start with $T_0 = 0$ and wait until the end point of the first of the $d_{U_1} + d_{U_2}$ half-edges is reached. This time is called $T_1$ and successive times at which further end points of ‘alive’ half-edges are reached are called $T_2, T_3, \ldots$. At $t = T_1$, we pair the exhausted half-edge, which we call $r_1$, with one of the $\ell_n - 1$ other half-edges at random; the found half-edge is called $P_{r_1}$. The formed edge $(r_1, P_{r_1})$ receives the weight of the exhausted half-edge $r_1$ and we connect the siblings of $P_{r_1}$ to the newly found vertex. The sibling half-edges receive i.i.d. weights from the sequence $(\xi_j)_{j \geq 1}$, whereas the weights of the other ‘alive’ half-edges are updated by subtracting $T_1$. We repeat the whole procedure by finding the minimum of the ‘alive’ half-edges, and after adding this minimal weight to $T_1$ we find the second epoch time $T_2$. We continue this procedure until all half-edges are attached to one of the SWT’s.
In general, the formed edge \((r_1, P_{r_1})\) at time \(t = T_1\) receives a weight with the correct distribution. However, this only occurs when \(r_1\) pairs with one of the \(\ell_n - (d_{U_1} + d_{U_2})\) so-called ‘free’ half-edges, i.e., half-edges connected to vertices which are not yet wetted. When \(r_1\) pairs with one of its \(d_{U_1} - 1\) sibling half-edges (and hence a self-loop occurs) or when \(r_1\) pairs with one of the \(d_{U_3} = \ell_n\) half-edges incident to vertex \(U_{3-i}\) (and hence a ‘collision’ edge occurs), then we do not know what weight we should assign to the self-loop or collision edge, because the half-edge to which \(r_1\) is paired is an alive half-edge and already had a weight. In order to resolve this issue, in the next section, we shall make sure that a weight is only assigned to one of the half-edges of an edge. This will be achieved by first investigating whether a half-edge is paired to a ‘free’ half-edge or to an ‘alive’ half-edge. In particular, we will change the order in which half-edges are paired. We are free to pair half-edges in any order we like and this property is used to remove self-loops, edges that close a cycle and collision edges beforehand. This way, all paths receive weights with the correct distribution, and after the completion of the entire construction we take the minimum of all connecting paths to find \(L_n\) and \(H_n\).

The removal of self-loops, edges that close a cycle and collision edges is done at the epoch times \(T_0, T_1, T_2, \ldots\). Conditionally on the number of ‘alive’ half-edges and ‘free’ half-edges, we know the success probabilities of Bernoulli random variables that determine whether a pairing results in attaching to a ‘free’ half-edge or to an ‘alive’ half-edge.

We will couple the \(\text{SWT}(\cdot)\) both to an \(n\)-dependent continuous-time branching process (CTBP) denoted by \(\text{BP}_n(\cdot)\) and to a CTBP \(\text{BP}(\cdot)\) whose driving offspring distribution is the size-biased degree distribution as in (1.12) and lifetimes having distribution \(F_c\). This results in a coupling \((\text{SWT}(t), \text{BP}_n(t), \text{BP}(t))\) on the same probability space \((\Omega, \mathcal{F}, \mathbb{P})\), where \(\text{SWT}(t)\) consists of the alive half-edges that are connected to \(U_1\) and \(U_2\) by paths of weights at most \(t\), as well as their residual lifetimes, while \(\text{BP}_n(t)\) contains the same information for the \(n\)-dependent CTBP and \(\text{BP}(t)\) for the \(n\)-independent CTBP.

Since there are a number of ingredients in this coupling, let us start by giving the reader an intuitive mental picture of the key actors in this coupling. In the first step of the coupling, which is explained in full detail in Section 2.2, we couple the forward degrees in the \(\text{SWT}(t)\) to the number of offspring in the branching processes \(\text{BP}_n(t)\) and \(\text{BP}(t)\). On one and the same probability space \((\Omega, \mathcal{F}, \mathbb{P})\), we introduce sequences of random variables \(B_k^{(n)}, (B_k)_{k \geq 1}, (Y_k^{(n)})_{k \geq 1}\) and \((X_k^{(n)})_{k \geq 1}\), and a sequence of stopping times \(\tau_k\).

The sequences \(B_k^{(n)}, (B_k)_{k \geq 1}\) are i.i.d. and will be used as the number of offspring in a branching process, where the first branching process depends on \(n\), while the second one is independent of \(n\). In the coupling, there is a strong dependence between \(B_k^{(n)}\) and \(B_k\) for any \(k\). The sequence \((Y_k^{(n)})_{k \geq 1}\) will correspond to the sequence of forward degrees, i.e., the degree minus one, as the liquid in \(\text{SWT}\) percolates through the graph, while \(X_k^{(n)}\) will be equal to \(Y_k^{(n)}\) minus the number of pairings that result in either a self-loop, a cycle or a collision edge. Using the stopping times \(\tau_k\), the \(k\)th variable \(X_k^{(n)}\) will be successfully coupled to \(B_{\tau_k}^{(n)}\) precisely when \(X_k^{(n)} = Y_k^{(n)}\) and \(Y_k^{(n)} = B_{\tau_k}^{(n)}\).

Since this coupling is not perfect, in the second step of the coupling performed in Section 2.3, we discuss the evolution of the processes \((\text{SWT}(t), \text{BP}_n(t), \text{BP}(t))\) on \(\Omega\), including the evolution of the children of the alive half-edges that are miscoupled. Finally, in Section 2.4, we state the main bounds on our coupling. After this high-level explanation, let us now give the details of our coupling construction.

### 2.2. Coupling forward degrees of the SWT

Before we start with the definition of the SWT’s on one probability space, we introduce an abstract procedure involving two sets, and a recursive sequence of samples drawn without replacement. This procedure is used repeatedly during the building of the SWT’s to remove occurring self-loops, edges that close a cycle and collision edges. The idea is as follows. Consider a partition of a set \([m]\) into \(A\) and \(B = A^c\). One can achieve a uniform draw from \([m]\) in two steps, first by performing a Bernoulli experiment with success probability \(p_A = |A|/m\); if the outcome of this experiment is one, then we draw an object uniformly from \(A\), otherwise we draw a uniform object from \(B\). In fact, we do not even have to
Recursion:

In the following procedure, we first need to set up some notation. This is formalized recursively defined. When doing so, we can think of this as ‘testing’ whether a half-edge creates a self-loop, cycle or collision edge, or whether it connects to a ‘free’ half-edge. To actually draw the latter uniform element. We will perform such a construction repeatedly, with \( A \) denoting the set of alive half-edges at appropriate stopping times and where the set \([m]\) is recursively defined. When doing so, we can think of this as ‘testing’ whether a half-edge creates a self-loop, cycle or collision edge, or whether it connects to a ‘free’ half-edge. This is formalized in the following procedure. We first need to set up some notation.

The procedure takes as its input one non-empty set, the “alive” set \( AS = \{a_1, a_2, \ldots, a_s\} \) having \( s \) elements, and the size of the “free” set \( N \). The elements \( a_j \in AS, j = 1, 2, \ldots, r \) for \( r \leq s \) are special. We will view them as a list (namely an ordered set) \( TS = (a_1, a_2, \ldots, a_r) \), of \( r \) elements.

Abusing notation, the procedure initializes with \( AS(0) := AS, TS(0) := TS \) and \( N(0) := N \) and we will sequentially update these sets and this number as follows using a sequence of conditionally independent Bernoulli random variables \( (\beta_i)_{1 \leq i \leq s} \) and a sequence of sets \( (S_i)_{i \geq 1} \):

**Procedure 2.1** (Preprocessing the matchings). (a) **Initialization:** Define the success probability and set \( S_1 \) as

\[
p_1 = \frac{|AS(0)| - 1}{|AS(0)| + N(0) - 1} \quad \text{and} \quad S_1 = AS \setminus \{a_1\} = \{a_2, \ldots, a_s\}. \tag{2.1}
\]

Let \( \beta_1 \sim \text{Bernoulli}(p_1) \).

(i) If \( \beta_1 = 1 \), then select element \( b_1 \) uniformly at random from the set \( S_1 \) and update the sets as \( AS(1) = AS(0) \setminus \{a_1, b_1\} \) and if \( b_1 \in TS(0) \) then \( TS(1) = TS(0) \setminus \{a_1, b_1\} \), else \( TS(1) = TS(1) \setminus \{a_1\} \). We do not change \( N(1) := N(0) \).

(ii) If \( \beta_1 = 0 \), then we do not select any element from \( S_1 \) and we update the sets as \( AS(1) = AS(0) \setminus \{a_1\} \) and \( TS(1) = TS(0) \setminus \{a_1\} \), while \( N(1) = N(0) - 1 \).

(b) **Recursion:** For \( k \geq 1 \) we proceed recursively as above, taking the first element at the front of the list \( TS(k) \), which, abusing notation, we still call \( a_{k+1} \) (note, this element may not be \( a_{k+1} \) in \( TS(0) \), if that element is already drawn at a previous time step) now defining

\[
p_{k+1} = \frac{|AS(k)| - 1}{|AS(k)| + N(k) - 1} \quad \text{and} \quad S_{k+1} = AS(k) \setminus \{a_k\}, \tag{2.2}
\]

generating \( \beta_{k+1} \sim \text{Bernoulli}(p_{k+1}) \) and proceeding as in (i) and (ii) above, with \( a_1, b_1, S_1 \) replaced by \( a_{k+1}, b_{k+1}, S_{k+1} \), respectively.

(c) **Termination:** We stop when the list equals the empty set, i.e., \( TS(k) = \emptyset \).

Let us give a brief and informal sketch of how we use Procedure 2.1. Consider the informal description in Section 2.1 of the liquid percolating through a network started from two vertices \( U_1 \) and \( U_2 \) simultaneously. Assume that at some time \( t \), the liquid from vertex \( U_i \), where \( i = 1, 2 \), hits a new vertex \( V \). The set of half-edges incident to \( V \), called \( HE_V \), except the one used by \( V \) to connect to \( SWT(t) \), are now deemed active since the flow has encountered this new vertex \( V \). Write \( AS = AH(t) \cup AH(2)(t) \cup HE_V \) for the collection of alive half-edges at this time, and \( TS = (HE_V) \) for the set of half edges incident to \( V \). Then the above procedure tests for each one of these newly added half-edges whether it pairs to a half-edge in \( AH(t) \), which corresponds to the “\( \beta_k = 1 \)” events, or instead connects to a new half-edge not in \( SWT(t) \cup SWT(2)(t) \), which corresponds to the “\( \beta_k = 0 \)” events. In the latter case, we actually do not connect the half-edge, but only record that the half-edge is paired to a free half-edge and thus decrease the number of free half-edges \( N(k) \) by 1. Further note that in each “\( \beta_k = 1 \)” event, the new edge created could either be (a) a self-loop or cycle when the half-edge pairs to an alive half-edge in \( SWT(t) \), namely the same cluster that sees \( V \) for the first time or (b) arguably more importantly, creates a collision edge when it is paired to a half edge in \( SWT(1)(t) \), the other cluster. These collision edges are the ones that potentially create the shortest path.

Let us now turn to the precise definition of the probability space for the coupling of the forward degrees of SWT and the associated branching processes. We start on one and the same probability space \( (\Omega, \mathcal{F}, \mathbb{P}) \) with the following ingredients:

(i) Two vertices \( U_1 \) and \( U_2 \) chosen at random from \( [n] \);
(ii) Label the $\ell_n$ half-edges by $[\ell_n]$ with the half-edges of vertex 1 labelled 1, 2, $\ldots$, $d_1$, the half-edges of vertex 2 labelled $d_1 + 1, \ldots, d_1 + d_2$, etc. We will require repeated draws with replacement from $[\ell_n]$, which results in an i.i.d. sequence $(\sigma_i)_{i \geq 1}$. We will also require a second sequence of i.i.d. draws $(\tilde{\sigma}_i)_{i \geq 1}$ that is independent of the draws $(\sigma_i)_{i \geq 1}$;

(iii) To each $\sigma_i$ and $\tilde{\sigma}_i$, we associate random variables $B_1^{(n)}$ and $\tilde{B}_1^{(n)}$ that correspond to the forward degree of the vertices incident to the half-edges $\sigma_i$ and $\tilde{\sigma}_i$. To each $B_1^{(n)}$ and $\tilde{B}_1^{(n)}$, we associate random variables $B_i$ and $\tilde{B}_i$, whose distributions only depend on $B_1^{(n)}$ and $\tilde{B}_1^{(n)}$ and not on any of the other randomness involved;

(iv) An i.i.d. sequence $(\xi_i)_{i \geq 1}$ of edge-weights with distribution $F_{\xi}$, and a second sequence of i.i.d. weights $(\tilde{\xi}_i)_{i \geq 1}$ that is independent of the edge-weights $(\xi_i)_{i \geq 1}$;

(v) Recall that vertex $j \in [n]$ had degree $d_j$. Recall the uniform choices $b_1, b_2, \ldots$ in Procedure 2.1 modulated by the values of the Bernoulli sequence $\beta_1, \beta_2, \ldots$. Analogously, we construct random variables $(b_j(1), \ldots, b_j(d_j))$, taking values in the set of half-edges $[\ell_n]$ modulated by a sequence of Bernoulli random variables $\beta_j(1), \ldots, \beta_j(d_j)$. The distribution of both these random variables will depend on $(U_1, U_2, (\sigma_i)_{i \geq 1}, (\tilde{\sigma}_i)_{i \geq 1})$. The precise laws of these ingredients will be specified as we sequentially apply Procedure 2.1 below.

Before using the above ingredients to construct SWT, let us first describe how they are used to construct the offspring of the branching processes BP$_n$ and BP. We define, for $i \geq 1$,

$$B_i^{(n)} = \sum_{j=1}^{n} (d_j - 1) \mathbb{1}_{\{d_1 + \ldots + d_j - 1 \leq d_1 + \ldots + d_j\}},$$

(2.3)

i.e., when $\sigma_i$ chooses one of the half-edges incident to vertex $j$, $B_i^{(n)}$ is the forward degree (i.e., degree minus one) of that vertex $j$. Obviously, the sequence $(B_i^{(n)})_{i \geq 1}$ is i.i.d. with common distribution given by

$$g_k^{(n)} = \mathbb{P}(B_i^{(n)} = k) = \frac{k + 1}{\ell_n} \sum_{j=1}^{n} \mathbb{1}_{\{d_j = k + 1\}}, \quad k \geq 0.$$

(2.4)

Note that $g_k^{(n)} = \mathbb{P}(D_n^* = k + 1)$, where $D_n^*$ has the same distribution as the size-biased version of $D_n$, the degree of a randomly selected vertex, see (1.7). Assuming Condition 1.1, we have that $g_k^{(n)} \to g_k$, as $n \to \infty$, where

$$g_k = \frac{(k + 1) f_{k+1}}{\sum_{j=1}^{\infty} j f_j}, \quad k \geq 0,$$

(2.5)

and where $f_j = F(j) - F(j - 1)$.

We next construct an i.i.d. sequence $(B_i)_{i \geq 1}$ with common distribution (2.5) by using the already constructed $(B_i^{(n)})_{i \geq 1}$ sequence as follows: For each $i \geq 1$, $B_i$ depends only on $B_i^{(n)}$ and is generated via the conditional distribution

$$\mathbb{P}(B_i = k \mid B_i^{(n)} = l) = \frac{p_{kl}^{(n)}}{\sum_{j=0}^{\infty} p_{lj}^{(n)}},$$

(2.6)

where

$$p_{kl}^{(n)} = \begin{cases} \min\{g_k, g_k^{(n)}\}, & \text{for } k = l, \\ (g_k - \min\{g_k, g_k^{(n)}\})(g_l^{(n)} - \min\{g_l, g_l^{(n)}\}) - \frac{1}{2} \sum_{j=0}^{\infty} |g_j - g_j^{(n)}|, & \text{for } k \neq l. \end{cases}$$

(2.7)

It is easy to check that $(B_i)_{i \geq 1}$ is an i.i.d. sequence of random variables having probability mass function $g_k$ in (2.5). In fact, the joint distribution $(p_{kl}^{(n)})_{k,l \geq 0}$ is the one that maximizes the coupling probability between the two probability mass functions $(g_k)_{k \geq 0}$ and $(g_k^{(n)})_{k \geq 0}$ (alternatively, the coupling that minimizes the total variation distance between the two distributions [39]).
Let us now proceed to the more involved construction of the shortest weight tree \( \text{SWT} \) using the above probabilistic ingredients. The main ingredient of our construction are the continuous-time processes of ‘alive’ half-edges \((A\!H(t))_{t \geq 0}\) and ‘free’ half-edges \((F(t))_{t \geq 0}\). We also introduce two new random sequences \((Y_{k}^{(n)})_{k \geq 1}\) and \((X_{k}^{(n)})_{k \geq 0}\). We will need an additional superscript \(i\) to denote whether \(Y_{k}^{(n)}\) and/or \(X_{k}^{(n)}\) belongs to the \( \text{SWT} \) of \( U_{i} \), \( i = 1, 2 \). The continuous-time processes \((A\!H(t))_{t \geq 0}\) and \((F(t))_{t \geq 0}\) only change at random times \( T_{0} = 0 < T_{1} < T_{2} < \ldots \) and therefore a full description of the continuous-time evolution can be given by a specification of how the random times above are constructed and how these processes “jump” at each of these times.

At time \( t = T_{0} \), we start by testing whether any of the half-edges \( d_{U_{i}} \) incident to \( U_{i} \), \( i = 1, 2 \), are paired to one another. This is performed vertex by vertex, and we start with \( U_{1} \). Let us define \( \text{HE}_{j} \), for \( j \in [n] \), as the set of \( d_{j} \) half-edges that belong to vertex \( j \). We define \( Y_{0}^{(n,1)} \) as the number of half-edges incident to \( U_{1} \), i.e.,

\[
Y_{0}^{(n,1)} = d_{U_{1}} = |\text{HE}_{U_{1}}|.
\]

Now put \( \text{AS} = \text{HE}_{U_{1}} \), \( \text{TS} = (\text{AS}) \), where the parentheses \((\cdot)\) indicate that we consider a list instead of a set, and \( \mathbf{N} = \ell_{n} - d_{U_{1}} \), and apply Procedure 2.1 to remove all half-edges from the total set of \( d_{U_{1}} \) half-edges that are part of a self-loop. We then define \( \text{RHE}_{U_{1}} \) as the set of unpaired half-edges after the self-loops incident to \( U_{1} \) are removed and

\[
X_{0}^{(n,1)} = |\text{RHE}_{U_{1}}|,
\]

as the number of unpaired half-edges of \( U_{1} \) after the self-loops have been removed. We attach i.i.d. weights to each of the half-edges in \( \text{RHE}_{U_{1}} \) by taking the first \( X_{0}^{(n,1)} \) weights from \((\xi_{i})_{i \geq 1}\).

We continue with the \( d_{U_{2}} \) half-edges incident to \( U_{2} \), and test whether they are paired to one of the \( X_{0}^{(n,1)} \) remaining half-edges incident to \( U_{1} \), or any of the \( d_{U_{2}} \) half-edges incident to \( U_{2} \). We do this by applying Procedure 2.1 with \( \text{AS} = \text{RHE}_{U_{1}} \cup \text{HE}_{U_{2}} \), \( \text{TS} = (\text{HE}_{U_{2}}) \) and

\[
\mathbf{N} = \ell_{n} - d_{U_{1}} - d_{U_{2}} - X_{0}^{(n,1)},
\]

which equals the total number of half-edges that are still available to be connected to (noting that the ones that are paired to the half-edges incident to \( U_{1} \) are no longer available). A self-loop is formed when during this test a half-edge is paired to one of the \( d_{U_{2}} \) sibling half-edges. A so-called collision edge is formed when during this test a half-edge is paired to one of the \( X_{0}^{(n,1)} \) remaining half-edges incident to vertex \( U_{1} \). The weight of this collision edge is the weight of the half-edge incident to \( U_{1} \), which it has already obtained in the previous step. A collision produces a path between vertices \( U_{1} \) and \( U_{2} \), which possibly is the minimal weight path between \( U_{1} \) and \( U_{2} \). We define \( \text{RHE}_{U_{2}} \) as the set of unpaired half-edges incident to vertex \( U_{2} \) after the removal of the self-loops and collision edges. Furthermore, we define

\[
Y_{0}^{(n,2)} = d_{U_{2}},
\]

and

\[
X_{0}^{(n,2)} = |\text{RHE}_{U_{2}}|,
\]

i.e., \( X_{0}^{(n,2)} \) denotes the number of unpaired half-edges of vertex \( U_{2} \) after the test for collision edges and self-loops has been performed. We attach i.i.d. weights to each of the half-edges in \( \text{RHE}_{U_{2}} \) by taking the first \( X_{0}^{(n,2)} \) available weights from the i.i.d. sequence \((\xi_{i})_{i \geq 1}\) (note that the first \( X_{0}^{(n,1)} \) weights have already been assigned to the half edges in \( \text{RHE}_{U_{1}} \)). By construction, the remaining \( X_{0}^{(n,1)} + X_{0}^{(n,2)} \) half-edges incident to the vertices \( U_{1}, U_{2} \) are paired to fresh vertices, i.e., vertices distinct from \( U_{1} \) and \( U_{2} \).

For the moment, we collect the possible collision edges at time \( T_{0} \), together with their weights, which is equal to the weight of the half-edge incident to \( U_{1} \) that forms one half of the collision edge, and continue with the description. All half-edges that are not paired to one of the other \( d_{U_{1}} + d_{U_{2}} - 1 \) half-edges incident to either \( U_{1} \) or \( U_{2} \) together form the set \( \text{AH}(0) \), the set of active half-edges at time 0, i.e.,

\[
\text{AH}(0) = \text{RHE}_{U_{1}} \cup \text{RHE}_{U_{2}}.
\]
For \( y \in AH(0) \), we define the height \( H(y) = 1 \) and its index \( I(y) = i \), if the half-edge \( y \) is connected to \( U_i \), \( i = 1, 2 \), and \( R_0(y) \) for the weight with distribution \( F_\xi \) that the half edge received earlier. This initiates the construction with

\[
\text{SWT}(0) = (y, H(y), I(y), R_0(y))_{y \in AH(0)},
\]

and we let \( \text{SWT}^{(i)}(0) = (y, H(y), R_0(y))_{y \in AH(0), I(y) = i} \), be the subset of \( \text{SWT}(0) \) that is connected to vertex \( U_i \), \( i = 1, 2 \).

After the above initialization, let us now describe how to construct the process \( \text{SWT}(t) = \text{SWT}^{(1)}(t) \cup \text{SWT}^{(2)}(t) \) and \( \text{SWT}^{(1)} \) with \( i = 1, 2 \), for general \( t > 0 \). Abusing notation, we call \( \text{SWT}^{(i)}(t) \) the shortest path tree emanating from vertex \( U_i \). Using the information \((\text{SWT}^{(i)}(s))_{0 \leq s \leq t} \), we can construct the genealogical tree representing how the liquid percolates from the source \( U_i \) but this process contains much more information including edge lengths encountered by the process. As for \( t = 0 \), the process \( \text{SWT}(t) \) has a set of ‘alive’ half-edges \( AH(t) \), which we formally define below. For \( y \in AH(t) \), we record its index \( I(y) \in \{1, 2\} \) if \( y \in \text{SWT}^{(i)(y)} \) and we let \( H(y) \) denote the graph distance of \( y \) to \( U_{I(y)} \) (viewing \((\text{SWT}^{(i)}(s))_{s \in [0,t]} \) as a tree). Further, for \( y \in AH(t) \), we let \( R_t(y) \) denote the residual lifetime of \( y \) at time \( t \). Then, we let

\[
\text{SWT}(t) = (y, H(y), I(y), R_t(y))_{y \in AH(t)}
\]

denote the set of alive half-edges together with their indices, their heights and residual lifetimes.

At a later state, we will also define \( BP_n(t) \) and \( BP(t) \), the CTBP analogs of \( \text{SWT}(t) \).

We next recursively define the evolution of \( (\text{SWT}(t))_{t \geq 0} \). Define \( T_1 = \min_{y \in AH(0)} R_0(y) \) and denote the half-edge equal to the argument of this minimum by \( y_0^* \), hence \( R_0(y_0^*) = \min_{y \in AH(0)} R_0(y) \). Since the distribution of the weights (lifetimes) admits a density \( f_\xi \), \( y_0^* \) is a.s. unique. Now set

\[
AH(t) = AH(0), \quad 0 \leq t < T_1,
\]

i.e., the active set remains unchanged during the interval \([0, T_1)\). This defines the shortest weight tree in (2.15) for \( 0 \leq t < T_1 \), where \( I(y) \) and \( H(y) \) are defined above and \( R_t(y) = R_0(y) - t \), \( 0 \leq t < T_1 \), denotes the remaining lifetime of half-edge \( y \) at time \( t \).

At time \( t = T_1 \), we continue by describing the pairing of the half-edge \( y_0^* \) with \( z_0 = P_{y_0^*} \) and at this place we will introduce the coupling between \( Y_1^{(n)} \) and \( B_1^{(n)} \) (see (2.3)). For a half-edge \( y \), let \( V_y \) denote the vertex incident to it. By construction, \( z_0 = P_{y_0^*} \) is chosen such that \( V_{z_0} \) is not equal to \( U_i \), \( i = 1, 2 \). This is achieved by taking

\[
\tau_1 = \min\{m \geq 1 : V_{\sigma_m} \neq U_1, V_{\sigma_m} \neq U_2\},
\]

and we define

\[
Y_1^{(n)} = B_1^{(n)} \quad \text{and} \quad z_0 = \sigma_{\tau_1}.
\]

When \( \tau_1 = 1 \), we see that \( Y_1^{(n)} = B_1^{(n)} \), while when \( \tau_1 > 1 \), the forward degree \( Y_1^{(n)} \) of the chosen vertex \( V_{z_0} \) is not successfully coupled to the random variable \( B_1^{(n)} \).

At time \( t = T_1 \), we remove \( y_0^* \) from the set \( AH(t) \). Then, for each of the \( dV_{z_0} - 1 \) other half-edges incident to vertex \( V_{z_0} \) we test, using Procedure 2.1, with

\[
\text{AS} = AH(t- \cup (\text{HE}_{V_{z_0}} \setminus \{z_0\}), \quad \text{TS} = (\text{HE}_{V_{z_0}} \setminus \{z_0\})
\]

and

\[
\mathbf{N} = \ell_n - d_{U_1} - d_{U_2} - d_{V_{z_0}} - |AH(0)|,
\]

which again has the interpretation of the number of available half-edges at the time of finding \( V_{z_0} \), whether it is part of a self-loop or paired to a half-edge from the set \( AH(t-) \). All half-edges incident to \( V_{z_0} \) that are part of a self-loop or incident to \( AH(t-) \) are removed from vertex \( V_{z_0} \); we also remove the involved half-edges from the set \( AH(t-) \). For all the remaining sibling half-edges \( x \) of \( z_0 \) we do the following: \( x \) is added to \( AH(t-) \), \( I(x) = I(y_0^*) \), \( H(x) = H(y_0^*) + 1 \), while \( R_{T_1}(x) \) is the next available i.i.d. lifetime from the sequence \((\xi_i)_{i \geq 1}\). We now set

\[
AH(t) = AH(T_1-), \quad T_1 \leq t < T_2,
\]

where \( T_2 = T_1 + \min_{y \in AH(T_1)} R_{T_1}(y) \), and where the minimizing half-edge is called \( y_1^* \).
We continue using induction, by defining $\text{AH}(t)$ and $\text{SWT}(t)$ during the random interval $[T_k, T_{k+1})$ for $k \geq 1$, given that the processes are defined on $[0, T_k)$. By construction, we know that $z_{k-1} = P_{y_{k-1}^*}$ is chosen such that $V_{z_{k-1}}$ is not equal to $U_i$, $i = 1, 2$ or one of the previously chosen vertices $V_{z_j}, 1 \leq j \leq k - 2$ (for $k = 1$, the latter is an empty condition). Therefore, we take

$$
\tau_k = \min\{m \geq \tau_{k-1} + 1: V_{\sigma_m} \notin \{U_1, U_2, V_{20}, \ldots, V_{z_{k-2}}\}\},
$$

and we define

$$
Y_k^{(n)} = B_{T_k}^{(n)} \quad \text{and} \quad z_{k-1} = \sigma_{\tau_k}.
$$

When $\tau_k = \tau_{k-1} + 1$, we see that $Y_k^{(n)} = B_{T_{k-1}+1}^{(n)}$, while for $\tau_k > \tau_{k-1} + 1$, the forward degree $Y_k^{(n)}$ of the chosen vertex $V_{z_{k-1}}$ is not coupled to the random variable $B_{T_{k-1}+1}^{(n)}$ and we call the vertex $V_{z_{k-1}}$ degree-mis coupled. At time $t = T_k$, we remove $y_{k-1}^*$ from the set $\text{AH}(t-)$. Then, for each of the $d_{V_{z_{k-1}}} - 1$ other half-edges incident to vertex $V_{z_{k-1}}$, we use Procedure 2.1, with

$$
\text{AS} = \text{AH}(t-) \cup (\text{HE}_{V_{z_{k-1}}} \setminus \{z_{k-1}\}), \quad \text{TS} = (\text{HE}_{V_{z_{k-1}}} \setminus \{z_{k-1}\}),
$$

and

$$
N = \ell_n - d_{u_1} - d_{u_2} - \sum_{j=0}^{k-1} d_{V_{z_j}} - |\text{AH}(T_{k-1})|,
$$

to test whether it is part of a self-loop or paired to a half-edge from the set $\text{AH}(t-)$. It is part of Procedure 2.1 that all half-edges incident to $V_{z_{k-1}}$ that are part of a self-loop or incident to $\text{AH}(t-)$ are removed from vertex $V_{z_{k-1}}$; we also remove the involved half-edges from the set $\text{AH}(t-)$. We will discuss the role of the half-edges incident to $V_{z_{k-1}}$ that are paired to half-edges in $\text{AH}(t-)\ldots$ in more detail below.

We sequentially order the remaining siblings half-edges of $z_{k-1}$ in an arbitrary order. In this order, we do the following: Let $x$ be one such half-edge of $V_{z_{k-1}}$, then add $x$ to $\text{AH}(t-)$, and set $I(x) = I(y_{k-1}^*)$ and $H(x) = H(y_{k-1}^*) + 1$, while $R_{T_k}(x)$ is the next in line of the i.i.d. sequence $(\xi_i)_{i \geq 1}$. We now set

$$
\text{AH}(t) = \text{AH}(T_k-), \quad T_k \leq t < T_{k+1},
$$

where $T_{k+1} = T_k + \min_{y \in \text{AH}(T_k)} R_{T_k}(y)$, and where the minimizing half-edge is called $y_{k}^*$. For $t \in [T_k, T_{k+1})$, we define $\text{SWT}(t)$ by (2.15), where $R_t(y) = R_{T_k}(y) - (t - T_k)$. Finally, we denote the number of the $d_{V_{z_{k-1}}} - 1$ other half-edges incident to vertex $V_{z_{k-1}}$ that do not form a self-loop and that are not paired to a half-edge from the set $\text{AH}(t-)$ by $X_k^{(n)}$. We say that the vertex $V_{z_{k-1}}$ is successfully degree-coupled to the corresponding individual in a branching process that has offspring $B_{T_{k-1}+1}^{(n)}$ (this will show up again in the next section) when both

$$
Y_k^{(n)} = B_{T_{k-1}+1}^{(n)} \quad \text{and} \quad X_k^{(n)} = X_k^{(n)},
$$

and otherwise is degree-mis coupled.

We finally denote $S_k^{(n)} = |\text{AH}(T_k)|$, so that $S_0^{(n)} = X_0^{(n,1)} + X_0^{(n,2)}$, while $S_k$ satisfies the recursion

$$
S_k^{(n)} = S_{k-1}^{(n)} + X_k^{(n)} - 1.
$$

This describes the evolution of $(\text{SWT}(t))_{t \geq 0}$.

**Cycle edges and collision edges.** At time $T_k$, $k \geq 1$, we find the half-edge $y_{k-1}^*$ that is paired to $z_{k-1} = P_{y_{k-1}^*}$, and for each of the other half-edges $x$ incident to $V_{z_{k-1}}$, we check, using Procedure 2.1, whether or not a self-loop has been formed or whether or not $P_x \in \text{AH}(T_k-)$ are special. Indeed, the edge $(x, P_x)$ creates a cycle when $I(x) = I(P_x)$, while $(x, P_x)$ completes a path between $U_1$ and $U_2$ when $I(x) = 3 - I(P_x)$. Precisely the latter edges can create the shortest-weight path between $U_1, U_2$. Let us describe these collision edges in more detail.

At time $T_k$ and when we create a collision edge consisting of $x$ and $P_x$, then we record

$$
\left(T_k, I(x), H(x), H(P_x), R_{T_k}(P_x)\right),
$$

(2.28)
where
\[ I(x) = I(y_{k-1}^x), \quad H(x) = H(y_{k-1}^*) + 1. \] (2.29)

Order the times at which collision edges occur as \( (T_{j}^{(\text{col})})_{j \geq 1} \), and let \( (x_j, P_{x_j}) \) be the corresponding collision edge (so that \( P_{x_j} \) is in the other SWT as \( x_j \)). If multiple collision edges are created at the same time, then order them arbitrarily. We will see that the probability of such events in the time scale of interest converges to zero as \( n \to \infty \). Write
\[
C := \left( T_{j}^{(\text{col})}, I(x_j), H(x_j), H(P_{x_j}), R_{T_{j}^{(\text{col})}}(P_{x_j}) \right)_{j \geq 1},
\] (2.30)

for the collection of all collision edges collected by the process.

It is possible (albeit unlikely) that multiple half-edges incident to \( V_{k-1} \) create collision edges, and if so, we collect all of them in the list in (2.30). With some abuse of notation we denote the \( j \)th collision edge by \((x_j, P_{x_j})\); here \( P_{x_j} \) is an alive half-edge and \( x_j \) the half-edge which pairs to \( P_{x_j} \). Note that, at the time \( t \) of creation of the collision edge, the weight of the half-edge has already been assigned to the half-edge \( P_{x_j} \), and the half-edge \( P_{x_j} \) has residual lifetime equal to \( R_{t}(P_{x_j}) \).

The weight of the (unique) path between \( U_1 \) and \( U_2 \) that passes through the edge \((x_j, P_{x_j})\) equals \( 2 T_{j}^{(\text{col})} + R_{T_{j}^{(\text{col})}}(P_{x_j}) \) and its hopcount is equal to \( H(x_j) + H(P_{x_j}) + 1 \), so that the shortest weight equals
\[
L_n = \min_{j \geq 1} [2 T_{j}^{(\text{col})} + R_{T_{j}^{(\text{col})}}(P_{x_j})].
\] (2.31)

Let \( I^* \) denote the minimizer of \( j \mapsto 2 T_{j}^{(\text{col})} + R_{T_{j}^{(\text{col})}}(P_{x_j}) \), then
\[
H_n = H(x_{I^*}) + H(P_{x_{I^*}}) + 1.
\] (2.32)

Of course, (2.31) and (2.32) need a proof, which we give now:

**Proof that \( L_n \) in (2.31), and \( H_n \) in (2.32) yield the minimal weight and hopcount, respectively.**

Observe that the weight of each path between \( U_1 \) and \( U_2 \) with weight \( L \) can be written in the form \( L = 2 T_{i}^{(\text{col})} + R_{T_{i}^{(\text{col})}}(P_{x_i}) \), for some \( i \geq 0 \). Indeed, let \((i_0 = U_1, i_1, i_2, \ldots, i_k = U_2)\) form a path with weight \( L \), and denote the weight on \((i_{j-1}, i_j)\) by \( \xi_{e_j} \), for \( 1 \leq j \leq k \). For \( k = 1 \), we obviously find \( \xi_{e_1} = 2 T_0 + \xi_{e_1} \). For general \( k \geq 1 \), take the maximal \( j \geq 0 \) such that \( \xi_{e_1} + \cdots + \xi_{e_j} \leq L/2 \). Then, since \( L = \sum_{s=1}^{k} \xi_{e_s} \), we have that \( \sum_{s=1}^{j} \xi_{e_s} \leq \sum_{s=j+1}^{k} \xi_{e_s} \), so that
\[
L = 2 \sum_{s=1}^{j} \xi_{e_s} + \left[ \sum_{s=j+1}^{k} \xi_{e_s} - \sum_{s=1}^{j} \xi_{e_s} \right],
\]

which is of the form \( L = 2 T_{j}^{(\text{col})} + R_{T_{j}^{(\text{col})}}(y) \), for some \( j \geq 0 \) and some half-edge \( y \). Note that in the construction of the SWT’s, instead of putting weight on the edges, we have given weights to half-edges instead. In the representation (2.31) full edge weight is given to the active half-edges and weight 0 to the ones to which they are paired. At time \( T_{j}^{(\text{col})} \) when a collision edge has been found, the path-weight of the edges belonging to the same vertex \( U_i \) as half-edge \( y^* \) add up to \( T_{j}^{(\text{col})} \), the path-weight of all completed edges connected to \( 3 - U_i \) together with the residual lifetime \( R_{T_{j}^{(\text{col})}}(P_{x_i}) \) of the half-edge \( P_{x_i} \) has to be added to \( T_{j}^{(\text{col})} \) in order to yield the total weight of the path between \( U_1 \) and \( U_2 \).

The proof of (2.32) follows because the number of edges of the path between \( U_1 \) and \( U_2 \) that passes through the collision edge \((x_j, P_{x_j})\) is equal to the sum of the heights of the vertices incident to \( x_j, P_{x_j} \), respectively, and we add 1 for the edge \((x_j, P_{x_j})\) itself. This completes the proof of the claim.

\(\blacksquare\)
2.3. Coupling: Process level. In the above, we have described the coupling between reduced
forward degrees \( (X_i^{(n)})_{i \geq 1} \) in SWT and i.i.d. random variables \((B_i^{(n)}, B_t)\) where \((B_i^{(n)})_{i \geq 1}\) has
marginal distribution (2.4) and \((B_i)_{i \geq 1}\) has marginal distribution (2.5), and they are coupled as
in (2.7). We have used this coupling to describe the evolution of \((\text{SWT}(t))_{t \geq 0}\), and at the end of
this process, we know of each vertex that is found by the liquid, whether it is successfully degree-
coupled or not. As long as no degree-miscouplings occur, this can be thought of as a coupling
between SWT and two CTBPs with lifetimes having distribution \(F_\xi\) and \((B_i^{(n)})_{i \geq 1}\) and
\((B_i)_{i \geq 1}\), respectively, but the evolutions will start to diverge as soon as degree-miscouplings
start to appear. We now extend this coupling.

Recall that the SWT\(^{(i)}\) consists of half-edges and their attributes, connected to \(U_i\), for \(i = 1, 2\). We
couple to each SWT\(^{(i)}\), \(i = 1, 2\), to an independent CTBP BP\(^{(i)}\), so that SWT is
coupled to BP\(_n\) which consists of two independent CTBPs, i.e., BP\(_n\) = (BP\(^{(1)}\), BP\(^{(2)}\)), as well
as to an \(n\)-independent limiting CTBP BP that also consists of two independent CTBPs, i.e.,
BP = (BP\(^{(1)}\), BP\(^{(2)}\)). If \(Y_k^{(n)}\) is the forward degree of vertex \(V_{z_k-1}\), then \(I(y_{k-1}^*)\) indicates to
which SWT the vertex belongs. We recall that we say that the vertex \(V_{z_k-1}\) in the SWT is
degree-miscoupled to the corresponding individual (which we also refer to as vertex) if

\[
Y_k^{(n)} \neq B_{r_{k-1}+1}^{(n)} \quad \text{or if} \quad X_k^{(n)} \neq Y_k^{(n)}.
\]

(2.33)

Vertices that are degree-miscoupled will appear both in the SWT as well as in the CTBP BP\(_n\).
However, after being degree-miscoupled, the evolution of vertices in the CTBP and SWT diverge,
as we explain now. For the SWT, we say that an alive half-edge is miscoupled if the shortest-
weight path to the vertex incident to that half-edge uses at least one degree-miscoupled vertex.
In particular, the evolution of the SWT is such that half-edges of degree-miscoupled vertices are
defined attached to miscoupled half-edges. The same is true for the CTBP BP\(_n\), that is,
offspring of degree-miscoupled individuals are by definition miscoupled.

The weights assigned to half-edges incident to miscoupled vertices in the SWT and individuals
in the CTBP are independent. For this, we have introduced a second sequence of i.i.d.
weights \((\xi_i)_{i \geq 1}\) that is independent of the edge-weights of correctly coupled half-edges \((\xi_i)_{i \geq 1}\).
Each time that a half-edge is found by the SWT, we perform Procedure 2.1 and the coupling to the CTBPs
BP\(_n\) and BP. When, instead, a half-edge is found by (one of the) CTBPs only, we pair it to a
uniformly chosen half-edge chosen from \([t_n]\) without replacement. These choices are determined
by the i.i.d. sequence \((\sigma_i)_{i \geq 1}\), and, from these, the random variables \(\hat{B}_t^{(n)}\) and \(\hat{B}_t\) are obtained
as explained in (2.3) and (2.7). We use the variables \(\hat{B}_t^{(n)}\) for the evolution of BP\(_n\), and \(\hat{B}_t\) for the
evolution of BP. Thus, the evolution of miscoupled individuals in the CTBPs BP\(_n\) and BP
is completely independent of the evolution of SWT. We note that each alive
individual \(y\) in AH\(_t\), \(A\_n(t)\) and \(A(t)\) has a residual lifetime \(R_y(t)\), as well as an index
\(I(y)\) indicating which subtree \(y\) is an element of and a height \(H(y)\) denoting the generation of \(y\).

Similarly to (2.15), we then define

\[
\text{BP}_n(t) = (y, I(y), H(y), R_y(t))_{y \in A\_n(t)}; \quad \text{BP}(t) = (y, I(y), H(y), R_y(t))_{y \in A(t)}.
\]

(2.34)

Since the objects in (2.34) are coupled to \((\text{SWT}(t))_{t \geq 0}\) in (2.15), this completes the coupling of the FPP processes \((\text{SWT}(t), \text{BP}_n(t), \text{BP}(t))_{t \geq 0}\) and defines the probability space \((\Omega, \mathcal{F}, \mathbb{P})\) on which
this coupling of \((\text{SWT}(t), \text{BP}_n(t), \text{BP}(t))\) lives. We let \((\mathcal{F}_t)_{t \geq 0}\) be the filtration generated by all the
randomness used in the construction up to time \(t\), i.e., \(\mathcal{F}_t\) contains all the information needed
to construct \((\text{SWT}(s), \text{BP}_n(s), \text{BP}(s))_{s \in [0,t]}\). Under this coupling law, we can speak of convergence in probability, and we shall frequently do this in the sequel.

**Summary of the coupling.** For completeness and future references, we resume how differences arise in the coupling. Degree-miscouplings arise due to three effects:

1. **MISC.-miscouplings** occur between the forward degree \(Y_k^{(n)}\) (which are not i.i.d. due to draws being without replacement) and the i.i.d. draws \((B_i^{(n)})_{i \geq 1}\), because \(\tau_k > \tau_{k-1} + 1\); and
2. **cycle-events** occur referring to self-loops or cycles that makes \(X_k^{(n)} < Y_k^{(n)}\). In these cases we remove the self-loop or the edge that gives rise to a cycle from the set of alive half-edges. This amounts to removing up to at most \(Y_k^{(n)} - X_k^{(n)}\) half-edges incident to vertex \(V_{2n-1}\), as well as up to at most \(Y_k^{(n)} - X_k^{(n)}\) half-edges to which they are paired from SWT.
3. **collision edges** are found. In this case, precisely one of the vertices to which the collision edge is incident is degree-miscoupled. We want to emphasize here that the degree-miscoupling caused by finding the collision edge at time \(T^{(c)}_j\) does not effect the coupling of the shortest-weight paths. When the collision edge is removed, we are left with two paths connecting \(U_i\) to one of the vertices incident to the two half-edges of which the collision edge consists. It should be checked that at any time prior to \(T^{(c)}_j\) each of these paths is not miscoupled, i.e., does not contain any earlier degree-miscoupled vertices.

In all these three cases, the vertices involved are called **degree-miscoupled**, and any further offspring of degree-miscoupled vertices (in the SWT or in the CTBP) are called **miscoupled**. Thus, any miscoupling gives rise to a tress of miscoupled children half-edges in the SWT, respectively, offspring in the CTBP.

**2.4. Main coupling results.** We consider the process coupling \((\text{SWT}(t), \text{BP}_n(t), \text{BP}(t))_{t \geq 0}\) defined in the previous section, as well as the associated filtration \((F_t)_{t \geq 0}\). We recall that \(\text{BP}_n(t) = (\text{BP}^{(1)}_n(t), \text{BP}^{(2)}_n(t))\) are two independent CTBPs starting with offspring distribution \(D_n\) in the first generation and offspring law \(B^{(n)} = D_n^* - 1\) in the second and further generations, and \(\text{BP}(t) = (\text{BP}^{(1)}(t), \text{BP}^{(2)}(t))\) which are two independent CTBPs starting with offspring distribution \(D\) in the first generation and offspring distribution \(B = D^* - 1\) in the second and further generations. For this coupling \((\text{SWT}(t), \text{BP}_n(t), \text{BP}(t))_{t \geq 0}\), we let \(\text{AH}(t)\) denote the set of miscoupled half-edges at time \(t\). With a slight abuse of notation, we write \(\text{SWT}(t) = |\text{AH}(t)|\) and \(|\text{SWT}(t)\triangle \text{BP}_n(t)| = |\text{AH}(t)\triangle \text{Al}_n(t)|\). Finally, we denote the set of all miscoupled half-edges and individuals up to time \(t\) by

\[
\bigcup_{s \in [0,t]} \text{SWT}(s) \triangle \text{BP}_n(s). \tag{2.35}
\]

In this section, we state two key propositions concerning the coupling. Proposition 2.2(a) shows that there exists some \(s_n \to \infty\) such that, w.h.p., there are no miscouplings up to time \(s_n\). In Proposition 2.2(b) and Proposition 2.3, we investigate the size of \(\text{SWT}(t)\) for \(t\) close to \(t_n = \log n/(2\alpha_n)\).

**Proposition 2.2** (Coupling the SWT to a BP).

(a) There exists \(s_n \to \infty\) such that, for the coupling defined in Sections 2.2-2.3,

\[
\mathbb{P}\left(\text{(SWT}(s)_{s \in [0,s_n]} = (\text{BP}_n(s))_{s \in [0,s_n]} = (\text{BP}(s))_{s \in [0,s_n]}\right) = 1 - o(1). \tag{2.36}
\]

Consequently, with \(W_{s_n}^{(i)} = e^{-\alpha_n s_n} |\text{SWT}^{(i)}(s_n)|\), \(i = 1, 2\),

\[
\lim_{\varepsilon \downarrow 0} \lim_{n \to \infty} \mathbb{P}\left(W_{s_n}^{(1)} \in [\varepsilon, 1/\varepsilon], W_{s_n}^{(2)} \in [\varepsilon, 1/\varepsilon]\bigg| W_{s_n}^{(1)} W_{s_n}^{(2)} > 0\right) = 1. \tag{2.37}
\]

(b) Let \(t_n = \log n/(2\alpha_n)\). For the coupling of \((\text{SWT}(s))_{s \geq 0}\) and \((\text{BP}_n(s))_{s \geq 0}\) defined in Sections 2.2-2.3, there exist sequences \(\varepsilon_n \to 0\) and \(B_n \to \infty\) such that, conditionally on \(\mathcal{F}_{s_n}\), and for
every \( t \leq t_n + B_n \),

\[
P \left( \left| \bigcup_{s \in [0,t]} \text{SWT}(s) \triangle \text{BP}_n(s) \right| \geq \varepsilon_n \sqrt{n} \mid F_{s_n} \right) \to 0.
\tag{2.38}
\]

The proof of Proposition 2.2 is deferred to Section 5. We warn the reader to beware for confusion between the (large) constant \( B_n \) and the i.i.d. random variables \( (B_i)_{i \geq 1} \). Fix the deterministic sequence \( s_n \to \infty \) from Proposition 2.2. Now let

\[
t_n = \frac{1}{2\alpha_n} \log n, \quad \bar{t}_n = \frac{1}{2\alpha_n} \log n - \frac{1}{2\alpha_n} \log \left( \mathcal{W}_{s_n}^{(1)} \mathcal{W}_{s_n}^{(2)} \right).
\tag{2.39}
\]

Note that \( e^{\alpha_n t_n} = \sqrt{n} \); it will turn out that both \( |\text{SWT}^{(i)}(t_n)| \), for \( i = 1, 2 \), are of order \( \sqrt{n} \). Further, it will turn out that collision edges start to appear when these clusters grow to be of this size. Consequently, the variable \( t_n \) denotes the typical time at which collision edges start appearing, and the time \( \bar{t}_n \) incorporates for stochastic fluctuations in the size of the SWT’s.

For \( i \in \{1, 2\} \), \( k \geq 0 \), and \( s, t \geq 0 \), we define

\[
|\text{SWT}^{(i)}(t, t + s)| = \left| \{ y \in \text{AH}(t) : I(y) = i, H(y) = k, R_t(y) \in [0, s) \} \right|,
\tag{2.40}
\]

as the number of alive half-edges at time \( t \) that (i) are in the SWT of vertex \( U_i \), (ii) have height \( k \), and (iii) have remaining (or residual) lifetime at most \( s \). We further write

\[
|\text{SWT}^{(i)}_{\leq k}(t, t + s)| = \left| \{ y \in \text{AH}(t) : I(y) = i, H(y) \leq k, R_t(y) \in [0, s) \} \right|,
\tag{2.41}
\]

for the number of alive half-edges that have height at most \( k \). To formulate the CLT for the height of vertices, we will choose

\[
k_n(t, x) = \frac{t}{\bar{v}_n} + x \sqrt{\frac{\sigma^2}{\bar{v}_n^3}},
\tag{2.42}
\]

where \( \bar{v}_n, \bar{v} \) and \( \sigma^2 \) are defined in (1.19).

Define the residual life-time distribution \( F_R \) to have density \( f_R \) given by

\[
f_R(x) = \frac{\int_0^\infty e^{-\alpha y} f_\xi(x + y) \, dy}{\int_0^\infty e^{-\alpha y} [1 - F_\xi(y)] \, dy} = \frac{\alpha \nu}{\nu - 1} \int_0^\infty e^{-\alpha y} f_\xi(x + y) \, dy.
\tag{2.43}
\]

Below, we let \( \Phi \) denote the standard normal distribution function. Finally, for a half-edge \( y \in \text{AH}(t) \), we let \( X_y^* = dv_y - 1 \).

**Proposition 2.3** (Ages and heights in SWT). Fix \( j \in \{1, 2\} \), and numbers \( x, y, t \in \mathbb{R}, s_1, s_2 > 0 \), all independent of \( n \). Then, conditionally on \( F_{s_n} \) and \( \mathcal{W}_{s_n}^{(1)} \mathcal{W}_{s_n}^{(2)} > 0 \),

(a) we have

\[
e^{-2\alpha_n t_n} |\text{SWT}^{(j)}_{\leq k_n(t_n, x)}(\bar{t}_n + t, \bar{t}_n + t + s_1)| |\text{SWT}^{(3-j)}_{\leq k_n(t_n, y)}(\bar{t}_n + t, \bar{t}_n + t + s_2)| \to \nu e^{2\alpha t} \Phi(x) \Phi(y) F_R(s_1) F_R(s_2),
\tag{2.44}
\]

(b) further

\[
e^{-2\alpha_n t_n} |\text{SWT}^{(j)}_{\leq k_n(t_n, x)}(\bar{t}_n + t, \bar{t}_n + t + s_1)| \sum_{v} X_v^* \mathbb{1}_{\{v \in \text{SWT}^{(3-j)}_{\leq k_n(t_n, y)}(\bar{t}_n + t, \bar{t}_n + t + s_2)\}} \to \nu e^{2\alpha t} \Phi(x) \Phi(y) F_R(s_1) F_R(s_2).
\tag{2.45}
\]

The proof of Proposition 2.3 is deferred to Section 6.
3. Main ingredient: Poisson Point Process limit

In this section, we state our main result that implies Theorems 1.2-1.3. To state this result we need some additional definitions.

Recall the collection of collision edges $\mathcal{C}$ from (2.30). Here the $j$th collision edge is given by $(x_j, P_{x,j})$, where $P_{x,j}$ is an alive half-edge and $x_j$ the half-edge which pairs to $P_{x,j}$. Rescaling time by $\tilde{t}_n$ (see (2.39)), we define

$$T_j^{(\text{col})} = T_j^{(\text{col})} - \tilde{t}_n, \quad \bar{H}_j^{(\alpha)} = \frac{H(x_j) - t_n/\nu_n}{\sqrt{\sigma^2 t_n/\nu^3}}, \quad \bar{H}_j^{(\delta_e)} = \frac{H(P_{x,j}) - t_n/\nu_n}{\sqrt{\sigma^2 t_n/\nu^3}},$$

(3.1)

and write the random elements $(\Xi_j)_{j \geq 1}$ with $\Xi_j \in \mathcal{S} := \mathbb{R} \times \{1, 2\} \times \mathbb{R} \times \mathbb{R} \times [0, \infty)$, by

$$\Xi_j = (T_j^{(\text{col})}, I(x_j), \bar{H}_j^{(\alpha)}, \bar{H}_j^{(\delta_e)}, R_j^{(\text{col})}(P_{x,j})).$$

(3.2)

Then, for sets $A$ in the Borel $\sigma$-algebra of the space $\mathcal{S}$, we define the point process

$$\Pi_n(A) = \sum_{j \geq 1} \delta_{\Xi_j}(A),$$

(3.3)

where $\delta_x$ gives measure 1 to the point $x$. Let $\mathcal{M}(\mathcal{S})$ denote the space of all simple locally-finite point processes on $\mathcal{S}$ equipped with the vague topology (see e.g. [28]). On this space one can naturally define the notion of weak convergence of a sequence of random point processes $\Pi_n \in \mathcal{M}(\mathcal{S})$. This is the notion of convergence referred to in the following theorem.

**Theorem 3.1** (PPP limit of collision edges). Consider the distribution of the point process $\Pi_n \in \mathcal{M}(\mathcal{S})$ defined in (3.3) conditioned on $\mathcal{F}_{s_n}$ and $W_{s_n}^{(1)}W_{s_n}^{(2)} > 0$, for $s_n$ as in Proposition 2.2. Then, as $n \to \infty$, $\Pi_n$ converges in distribution to a Poisson Point Process (PPP) $\Pi$ with intensity measure

$$\lambda(dt \times dx \times dy \times dr) = \frac{2\nu f_s(0)}{E[D]} e^{2\alpha t} \times \{1/2, 1/2\} \otimes \Phi(dx) \otimes \Phi(dy) \otimes F_H(dr).$$

(3.4)

Theorem 3.1 will be proved in Section 7.

**Completion of the proof of Theorems 1.2 and 1.3.** Let us now prove Theorem 1.2 subject to Theorem 3.1. First of all, by (3.1), (2.31) and (2.32),

$$\left( H_n - \frac{1}{\alpha_n \rho_n} \log n, L_n - \frac{1}{\alpha_n} \log n \right)$$

(3.5)

is a continuous function of the point process $\Pi_n$, and, therefore, by the continuous mapping theorem, the above random vector converges in distribution to some random limit $(Z, Q)$.

Recall that $I^*$ denotes the minimizer of $i \mapsto 2T_i^{(\text{col})} + R_i^{(\text{col})}(P_{x,j})$. By (2.31), the weight $L_n$ as well as the value of $I^*$, are functions of the first and the last coordinates of $\Pi_n$. The hopcount $H_n$ is a function of the third and the fourth, instead. By the product form of the intensity in (3.4), we obtain that the limits $(Z, Q)$ are independent. Therefore, it suffices to study their marginals.

We start with the limit distribution of the hopcount. By (3.1) and (2.32),

$$\frac{H_n - \frac{1}{\alpha_n \rho_n} \log n}{\sqrt{\frac{\sigma^2}{\rho_n} \log n}} = \frac{1}{2} \sqrt{2} \bar{H}_i^{(\alpha)} + \frac{1}{2} \sqrt{2} \bar{H}_i^{(\delta_e)} + o_\nu(1).$$

(3.6)

By Theorem 3.1, the random variables $(\bar{H}_i^{(\alpha)}, \bar{H}_i^{(\delta_e)})$ converge to two independent standard normals, so that also the left-hand side of (3.6) converges to a standard normal.

The limit distribution of the weight $L_n$ is slightly more involved. By (2.39), (2.31) and (3.1),

$$L_n - \frac{1}{\alpha_n} \log n = L_n - 2t_n = L_n - 2\tilde{t}_n - \frac{1}{\alpha_n} \log(W_{s_n}^{(1)}W_{s_n}^{(2)})$$

(3.7)

$$= - \frac{1}{\alpha_n} \log(W_{s_n}^{(1)}W_{s_n}^{(2)}) + \min_{i \geq 1} \left[ 2\nu f_s^{(\text{col})} + R_{i}^{(\text{col})}(P_{x,i}) \right].$$
By Proposition 2.2, \((W^{(3)}_n, W^{(2)}_n) \xrightarrow{d} (W^{(1)}, W^{(2)})\), which are two independent copies of the random variable in (1.21). Hence,
\[
L_n - \frac{1}{\alpha_n} \log n \xrightarrow{d} - \frac{1}{\alpha} \log(\mathbb{W}^{(1)}W^{(2)}) + \min\{2\pi_i + R_i\},
\]
(3.8)
where \((\pi_i)_{i \geq 1}\) is a PPP with intensity \(\frac{2nf_R(0)}{\mathbb{E}[D]}e^{\alpha x}dt\), and \((R_i)_{i \geq 1}\) are i.i.d. random variables with distribution function \(F_R\) independently of \((\pi_i)_{i \geq 1}\).

We next identify the distribution of \(M = \min_{i \geq 1}\{2\pi_i + R_i\}\). First, \((2\pi_i)_{i \geq 1}\) forms a Poisson process with intensity \(\frac{2nf_R(0)}{\mathbb{E}[D]}e^{\alpha x}dt\). According to [36, Example 3.3 on page 137] the point process \((2\pi_i + R_i)_{i \geq 1}\) is a non-homogeneous Poisson process with mean-measure the convolution of \(\mu(-\infty, x] = \int_{-\infty}^x \frac{f_R(0)}{\mathbb{E}[D]} e^{\alpha x} dt\) and \(F_R\). Hence \(\mathbb{P}(M \geq x)\) equals the Poisson probability of 0, where the parameter of the Poisson distribution is \((\mu \ast F_R)(x)\), so that
\[
\mathbb{P}(M \geq x) = \exp\{-\frac{\nu f_R(0)}{\mathbb{E}[D]} e^{\alpha x} \int_0^x F_R(z)e^{-\alpha z} dz\}.
\]
(3.9)
Let \(\Lambda\) have a Gumbel distribution, i.e., \(\mathbb{P}(\Lambda \leq x) = e^{-e^{-x}}, x \in \mathbb{R}\), then, from (3.9),
\[
M = \min_{i \geq 1}\{2\pi_i + R_i\} \xrightarrow{d} -\alpha^{-1}\Lambda - \alpha^{-1}\log(\nu f_R(0)B/\mathbb{E}[D]),
\]
(3.10)
with \(B = \int_0^\infty F_R(z)e^{-\alpha z} dz\). In the following lemma, we simplify these constants:

**Lemma 3.2 (The constant).** The constants \(B = \int_0^\infty F_R(z)e^{-\alpha z} dz\) and \(f_R(0)\) are given by
\[
B = \bar{\nu}/(\nu - 1), \quad f_R(0) = \alpha/(\nu - 1).
\]
(3.11)
Consequently, the constant \(c\) in the limit variable (1.23) equals
\[
c = -\log(\nu f_R(0)B/\mathbb{E}[D]) = \log(\mathbb{E}[D](\nu - 1)^2/(\alpha \nu \bar{\nu})).
\]
(3.12)
**Proof.** According to (2.43) and (1.15),
\[
f_R(0) = \frac{\alpha \nu}{\nu - 1} \int_0^\infty e^{-\alpha y} f_\xi(y) dy = \alpha/(\nu - 1).
\]
(3.13)
For \(B\), we use partial integration and substitution of (2.43). This yields
\[
B = \int_0^\infty F_R(z)e^{-\alpha z} dz = \frac{1}{\alpha} \int_0^\infty f_R(z)e^{-\alpha z} dz = \frac{\nu}{\nu - 1} \int_0^\infty e^{-\alpha z} \int_0^\infty e^{-\alpha y} f_\xi(y + z) dy dz
\]
\[
= \frac{\nu}{\nu - 1} \int_0^\infty s f_\xi(s)e^{-\alpha s} ds = \frac{1}{(\nu - 1)} \int_0^\infty s F_\xi(ds) = \bar{\nu}/(\nu - 1).
\]
(3.14)
This completes the proof of Theorems 1.2 and 1.3 subject to Theorem 3.1.

**4. Height CLT and residual lifetime for CTBP**

In this section, we set the stage for the proof of Proposition 2.3 for CTBPs. We make use of second moment methods similar to the ones in [20, 23, 24, 37], but with a suitable truncation argument to circumvent the problem of infinite-variance offspring distributions.

As in the first part of Section 1.3, we consider a (standard) CTBP process [20, Chapter 6], with lifetime distribution \(F_\xi\) admitting a density \(f_\xi\), and random offspring \(X = X_0\) satisfying (1.13) and the \(X \log X\) in (1.14). We define
\[
\eta = \nu \int_0^\infty e^{-2\alpha s} dF_\xi(s), \quad \text{and} \quad m_j = K \eta^{-j}, \ j \geq 1,
\]
(4.1)
for some \(K > 1\). Note that \(\eta \in (0, 1)\), since \(\alpha\) is such that \(\nu \int_0^\infty e^{-\alpha s} dF_\xi(s) = 1\). The truncated CTBP BP\((\alpha)\) has for each individual in generation \(j\) offspring \((X \wedge m_j)\) instead of \(X\).

We denote the number of alive individuals in the CTBP at time \(t\) by \(|BP(t)|\). By \(|BP_k(t)|\), \(|BP_k([t, t + s])|\), we denote the number of alive individuals in generation \(k\) at time \(t\), number of alive individuals in generation \(k\) at time \(t\) with residual lifetime at most \(s\), respectively. We
warn the reader that $|\text{BP}_k(t)|$ refers to the number of individuals in generation $k$, and not to the $n$-dependence. When dealing with $n$-dependent CTBPs, we will use the notation $|\text{BP}_{n,k}(t)|$ instead.

Here the generation of the first individual equals 0, and the generation of its offspring is equal to 1, etc. For the truncated process $\text{BP}^{(n)}(t)$, we define, analogously to the definitions above, $|\text{BP}^{(n)}_k(t)|$, $|\text{BP}^{(n)}_{k}(t+t+s)|$. Furthermore,

$$|\text{BP}^{(n)}_{\leq k}[t, t+s]| = \sum_{j=0}^{k} |\text{BP}^{(n)}_j[t, t+s]|, \quad |\text{BP}^{(n)}_{k}[t, t+s]| = \sum_{j=0}^{\infty} |\text{BP}^{(n)}_j[t, t+s]|.$$  \hspace{1cm} (4.2)

A key ingredient to the proof of Proposition 2.3 is Proposition 4.1 below:

**Proposition 4.1** (First and second moment CLT). Consider the branching process $\text{BP}(t)$ introduced above, with i.i.d. lifetimes $F_t$ admitting a density and random offspring $X$ satisfying $\nu = \mathbb{E}[X] > 1$, and $\mathbb{E}[X \log(X)_+] < \infty$. Choose $m_j = K_{\eta}^{-j}$ as in (4.1). Then, with $A = (\nu - 1)/(\alpha \nu)$,

(a) $$\lim_{t \to \infty} e^{-\alpha t} \mathbb{E}[|\text{BP}(t)|] = A, \quad \lim_{K \to \infty} \limsup_{t \to \infty} e^{-\alpha t} \mathbb{E}[|\text{BP}(t)| - |\text{BP}^{(n)}(t)|] = 0,$$ \hspace{1cm} (4.3)

(b) there exists a constant $C > 0$, such that uniformly in $t \in [0, \infty)$,

$$e^{-2\alpha t} \mathbb{E}[|\text{BP}^{(n)}(t)|^2] \leq CK,$$ \hspace{1cm} (4.4)

(c) $$\lim_{K \to \infty} \lim_{t \to \infty} e^{-\alpha t} \mathbb{E}[|\text{BP}^{(n)}_{\leq k(t, x)}[t, t+s]|] = A\Phi(x)F_R(s),$$ \hspace{1cm} (4.5)

where $F_R$ is defined through (2.43) and $k(t, x) = t/\nu + x \sqrt{\alpha^2/(\nu)}$.

(d) Replace in the above statements $\text{BP}$ by $\text{BP}_n$, with offspring $X_n$, depending on $n$ in such a way that $X_n \overset{d}{\to} X$, $\nu_n = \mathbb{E}[X_n] \to \mathbb{E}[X]$ and $\sum_n \mathbb{E}[X_n \log(X_n / K_n)_+] = 0$, for any $K_n \to \infty$. Furthermore, now define $m_j$ by $m_j = K_n \eta^{-j}$, with $\eta_n = \nu_n \int_0^{\infty} e^{-2\alpha s} dF_{\xi}(s)$, and replace $k(t, x)$ by $k_n(t, x)$ defined in (2.42). Then Part (a) and Part (c) hold with $\alpha = \alpha_n$ and $t = t_n$ and with the limits replaced by $\lim_{n \to \infty}$, for any sequence $t_n \to \infty$. Similarly, under these conditions and substitutions, Part (b) holds for all $n \geq 1$, with $K$ replaced by $K_n$, uniformly in $t$.

**Proof.** We start by proving Proposition 4.1(a). The first claim of Part (a) is proved in [20, Theorem 17.1]. We bound the first moment of the difference between the truncated and the original branching process. Let $\nu^{(j)} = \mathbb{E}[X \wedge m_j]$. We compute that for $t > 0$,

$$e^{-\alpha t} \mathbb{E}\left[ \sum_{k=0}^{\infty} |\text{BP}^k(t) - |\text{BP}^{(n)}_k(t)|| \right] = e^{-\alpha t} \sum_{k=0}^{\infty} \left[ \nu^k \prod_{j=1}^{k} \nu^{(j)} \right] \left[ F^{*k}_{\xi}(t) - F^{*(k+1)}_{\xi}(t) \right],$$ \hspace{1cm} (4.6)

where $F^{*k}_{\xi}$ is the $k$-fold convolution of $F_{\xi}$, where, by convention, $F^{*0}_{\xi}(t) = 1$ for every $t \geq 0$. In order to bound the differences $\nu^k \prod_{j=1}^{k} \nu^{(j)}$, we rely on the following lemma:

**Lemma 4.2** (Effect of truncation on expectation CTBP). Under the conditions of Proposition 4.1, uniformly in $k \geq 1$,

$$[1 - \prod_{j=1}^{k} \frac{\nu^{(j)}}{\nu}] \leq (\log(1/\eta))^{-1} \mathbb{E}[X \log(X/K)_+] = o_K(1),$$ \hspace{1cm} (4.7)

where $o_K(1)$ denotes a quantity that converges to zero as $K \to \infty$.

**Proof.** Since $\nu^{(j)} \leq \nu$, for all $j \geq 1$, it is easily shown by induction that

$$1 - \prod_{j=1}^{k} \frac{\nu^{(j)}}{\nu} \leq \sum_{j=1}^{k} \left(1 - \frac{\nu^{(j)}}{\nu}\right) \leq \sum_{j=1}^{\infty} \left(1 - \frac{\nu^{(j)}}{\nu}\right).$$ \hspace{1cm} (4.8)
Now, using that $\nu > 1$,
\begin{equation}
\sum_{j=1}^{\infty} \left(1 - \frac{\nu(j)}{\nu}\right) \leq \sum_{j=1}^{\infty} \mathbb{E}[X1_{\{X>m_j\}}] = \mathbb{E}[X \sum_{j=1}^{\infty} 1_{\{m_j<X\}}],
\end{equation}
and we note that the number of $j$ for which $m_j = K\eta^{-j} < x$ is at most $[\log (x/K)/\log (1/\eta)] \lor 0$. Therefore, the inequality in (4.7) holds. Since $\mathbb{E}[X \log (X/K)_+] = o_K(1)$, the equality in (4.7) follows.

By Lemma 4.2 and (4.6),
\begin{equation}
\exp(-\alpha t) \mathbb{E}\left[\sum_{k=1}^{\infty} |\mathbb{B}^0_k(t)| - |\mathbb{B}^0_k(t^\ast)|\right] = o_K(1) \exp(-\alpha t) \mathbb{E}\left[\sum_{k=1}^{\infty} |\mathbb{B}^0_k(t)|\right] = o_K(1),
\end{equation}
which completes the proof of Proposition 4.1(a).

We continue with the proof of the second moment estimate in Proposition 4.1(b). We follow the proof in [37], keeping attention to the truncation. We introduce the generating functions
\begin{equation}
h(s) = \mathbb{E}[s^X], \quad h_j(s) = \mathbb{E}[s^{X\land m_j}],
\end{equation}
where $m_j$ is given by (4.1). Parallel to calculations in the proof of [37, Lemma 4],
\begin{equation}
\mathbb{E}[|\mathbb{B}^0(t)|^2] = h''(1)(\mathbb{E}[|\mathbb{B}^0(t^\ast)|])^2 \ast F_{\xi} + h'_1(1)\mathbb{E}[|\mathbb{B}^0(t^\ast)|] \ast F_{\xi},
\end{equation}
where $\bar{m}_1 = (m_2, m_3, \ldots)$ is $\bar{m}$ with the first element removed, and where for simplicity of reading the argument $t$ has been left out. Transforming to
\begin{equation}
|\mathbb{B}^0(t)| = \exp(-\alpha t)|\mathbb{B}^0(t)|,
\end{equation}
we obtain, after multiplying both sides of (4.12) by $e^{-2\alpha t}$,
\begin{equation}
\mathbb{E}[|\mathbb{B}^0(t)|^2] = \frac{\eta h''(1)}{\nu}(\mathbb{E}[|\mathbb{B}^0(t^\ast)|])^2 \ast Q + \frac{\eta h'_1(1)}{\nu}\mathbb{E}[|\mathbb{B}^0(t^\ast)|] \ast Q,
\end{equation}
where
\begin{equation}
F_{\xi}(t) = \nu \int_0^t e^{-\alpha y} dF_{\xi}(y), \quad Q(t) = \eta^{-1} \int_0^t e^{-\alpha y} dF_{\xi}(y) = \eta^{-1} \nu \int_0^t e^{-2\alpha y} dF_{\xi}(y),
\end{equation}
and where we recall that $\eta = \int_0^\infty e^{-\alpha y} dF_{\xi}(y) < 1$ and $\nu = h'(1)$. Iteration of (4.14) yields
\begin{equation}
\mathbb{E}[|\mathbb{B}^0(t)|^2] = \sum_{j=1}^{\infty} f_1 \cdots f_{j-1} e_j (\mathbb{E}[|\mathbb{B}^0(t^\ast)|])^2 \ast Q^j,
\end{equation}
where
\begin{equation}
e_j = \frac{\eta h''(1)}{\nu}, \quad f_j = \frac{\eta h'_1(1)}{\nu},
\end{equation}
and where $\bar{m}_j = (m_{j+1}, m_{j+2}, \ldots)$. Obviously,
\begin{equation}
\mathbb{E}[|\mathbb{B}^0(t)|^2] \leq \mathbb{E}[|\mathbb{B}^0(t^\ast)|^2] \leq \mathbb{E}[|\mathbb{B}^0(t)|] \to A,
\end{equation}
by Part (a). Hence, provided that the sum $\sum_{j=1}^{\infty} f_1 \cdots f_{j-1} e_j$ converges, which we will establish in Lemma 4.3 below, we have that, uniformly in $t$,
\begin{equation}
\mathbb{E}[|\mathbb{B}^0(t)|^2] \leq C \sum_{j=1}^{\infty} f_1 \cdots f_{j-1} e_j,
\end{equation}
for some constant $C \geq A^2$.

**Lemma 4.3** (Effect of truncation on variance CTBP). For $m_j = K\eta^{-j}$, and with $\nu = \mathbb{E}[X] > 1$,
\begin{equation}
\sum_{j=1}^{\infty} f_1 \cdots f_{j-1} e_j \leq \frac{2\nu K}{1 - \eta},
\end{equation}
where
Proof. We bound \( f_j \leq \eta \), and
\[
e_j \leq \eta \mathbb{E}[(X \wedge m_j)^2] = \eta m_j^2 \mathbb{P}(X > m_j) + \mathbb{E}[X^2 \mathbb{1}_{\{X \leq m_j\}}],
\]
so that
\[
\sum_{j=1}^{\infty} f_1 \ldots f_{j-1} e_j \leq \sum_{j=1}^{\infty} m_j^2 \mathbb{P}(X > m_j) \eta^j + \sum_{j=1}^{\infty} \mathbb{E}[X^2 \mathbb{1}_{\{X \leq m_j\}}] \eta^j.
\]
We bound both terms separately. The first contribution equals
\[
K^2 \sum_{j=1}^{\infty} \mathbb{P}(X > K \eta^{-j}) \eta^{-j} = K^2 \mathbb{E}[\sum_{j=1}^{\infty} \eta^{-j} \mathbb{1}_{\{K \eta^{-j} < X\}}] = K^2 \mathbb{E}\left[ \frac{\eta^{-a(X)} - 1}{1 - \eta} \right],
\]
where \( a(x) = \max\{j : K \eta^{-j} < x\} = \lfloor \log(x/K)/\log(1/\eta) \rfloor \). Therefore, \( \eta^{-a(X)} \leq X/K \), so that
\[
\sum_{j=1}^{\infty} m_j^2 \mathbb{P}(X > m_j) \eta^j \leq \frac{K^2}{1 - \eta} \mathbb{E}[X/K] = \frac{K \nu}{1 - \eta}.
\]
The second contribution is bounded in a similar way as
\[
\sum_{j=1}^{\infty} \mathbb{E}[X^2 \mathbb{1}_{\{X \leq m_j\}}] \eta^j = \mathbb{E}\left[ \sum_{j=1}^{\infty} X^2 \eta^j \mathbb{1}_{\{X \leq K \eta^{-j}\}} \right] = \mathbb{E}\left[ X^2 \sum_{j=1}^{\infty} \eta^j \right] = \mathbb{E}\left[ \frac{X^2 \eta^h(X)}{1 - \eta} \right],
\]
where \( h(x) = \min\{j : K \eta^{-j} \geq x\} \), so that \( \eta^h(X) \leq K/X \). Therefore,
\[
\sum_{j=1}^{\infty} \mathbb{E}[X^2 \mathbb{1}_{\{X \leq m_j\}}] \eta^j \leq \frac{K \mathbb{E}[X]}{1 - \eta} = \frac{K \nu}{1 - \eta}.
\]

Proposition 4.1 (b) follows by combining (4.19) and (4.20).
For Proposition 4.1(c), we start by showing that
\[
e^{-\alpha t} \sum_{j=0}^{k(t,x)} \mathbb{E}[\|BP_j[t,t+s]\|] \to A \Phi(x) F_R(s).
\]
Observe that \( |BP[t,t+s]| = \sum_{j=0}^{\infty} |BP_j[t,t+s]| \) is the total number of alive individuals at time \( t \), with residual lifetime at most \( s \), so that from [20, Lemma 2, Appendix Chapter VI], on the renewal equation
\[
\mathbb{E}[|BP[t,t+s]|] = F_\xi(t+s) - F_\xi(t) + \nu \int_0^\infty \mathbb{E}[|BP(t-y,t+s-y)|] dF_\xi(y),
\]
we readily obtain (compare the derivation of [20, Theorem 24.1]),
\[
\lim_{t \to \infty} e^{-\alpha t} \mathbb{E}[|BP[t,t+s]|] = \lim_{t \to \infty} e^{-\alpha t} \sum_{j=0}^{\infty} \mathbb{E}[|BP_j[t,t+s]|] = AF_R(s),
\]
with \( A = (\nu - 1)/(\alpha \nu \bar{v}) \) as given in the proposition. For fixed \( s > 0 \), define
\[
|BP_{>m}[t,t+s]| = \sum_{j=m+1}^{\infty} |BP_j[t,t+s]| = \sum_{j=m+1}^{\infty} e^{-\alpha t} |BP_j[t,t+s]|.
\]
Then, (4.27) follows if we show that
\[
\mathbb{E}[|BP_{>k(t,x)}[t,t+s]|] \to AF_R(s) - AF_R(s) \Phi(x) = AF_R(s) \Phi(-x).
\]
Conditioning on the lifetime (with cumulative distribution function equal to \( F_\xi \)) of the first individual,
\[
\mathbb{E}[|BP_j[t,t+s]|] = \nu \int_0^t \mathbb{E}[|BP_{j-1}[t-y,t+s-y]|] dF_\xi(y).
\]
Changing to $\overline{\mathbb{BP}}_j$ and $\tilde{F}_\xi$ and iteration of (4.31) yields
\[
\mathbb{E}[[\overline{\mathbb{BP}}_{k(t,x)}(t, t + s)] = \int_0^t \mathbb{E}[[\overline{\mathbb{BP}}[t - y, t - y + s])] \, dF_{k(t,x)+1}(y),
\] (4.32)
where $\tilde{F}_\xi$ is the $j$-fold convolution of $\tilde{F}_\xi$, and hence the distribution function of the independent sum of $j$ copies of a random variable each having cumulative distribution function. $\tilde{F}_\xi$. This is the point where we will use the CLT. Take an arbitrary $\varepsilon > 0$ and take $t_0$ so large so that for $t > t_0$,
\[
|\mathbb{E}[[\overline{\mathbb{BP}}[t, t + s]] - AF_{R}(s)| \leq \varepsilon.
\] (4.33)

Then,
\[
\mathbb{E}[[\overline{\mathbb{BP}}_{k(t,x)}(t, t + s)] - AF_{R}(s)\Phi(-x)] \leq \varepsilon F_{k(t,x)+1}(t) + AF_{R}(s)\tilde{F}_{k(t,x)+1}(t - \Phi(-x))
\]
\[+ \int_{t-t_0}^t \mathbb{E}[[\overline{\mathbb{BP}}[t - y, t - y + s]] - AF_{R}(s)] \, d\tilde{F}_{k(t,x)+1}(y).
\] (4.34)

The last term vanishes since $\mathbb{E}[[\overline{\mathbb{BP}}[t, t + s]]$ is uniformly bounded and $F_{k(t,x)}(t) - F_{k(t,x)}(t-t_0) = o(1)$, as $t \to \infty$. Furthermore, with $m = k(t,x) \to \infty$,
\[
k(t,x) \sim \frac{t}{\bar{\nu}} + x \sqrt{\frac{t}{\bar{\nu}^2}} \iff t \sim m\bar{\nu} - x\bar{\sigma}m.
\] (4.35)

As a result, by the CLT and the fact that $\bar{\nu}$ and $\bar{\sigma}^2$ are the mean and the variance of the distribution function $\tilde{F}_\xi$,
\[
\lim_{t \to \infty} \tilde{F}_{k(t,x)}(t) = \Phi(-x).
\] (4.36)

Together with (4.34), this proves the claim in (4.30), and hence (4.27). Finally we use the second statement of Part (a) to show that
\[
e^{-at} \sum_{j=0}^{k(t,x)} \mathbb{E}[[\overline{\mathbb{BP}}_j(t, t + s)] - e^{-at} \sum_{j=0}^{k(t,x)} \mathbb{E}[[\overline{\mathbb{BP}}_j(t, t + s)]
\]
\[\leq e^{-at}(\mathbb{E}[[\overline{\mathbb{BP}}(t)] - \mathbb{E}[[\overline{\mathbb{BP}}(t)]] \to 0,
\]
as first $t \to \infty$ and then $K \to \infty$. This shows Proposition 4.1(c).

We continue with the proof of Proposition 4.1(a) for the $n$-dependent CTBP. We denote the number of alive individuals at time $t$ in the $n$-dependent CTBP by $\overline{\mathbb{BP}}_n(t)$. We then have to show that for any sequence $t_n \to \infty$, as $n \to \infty$,
\[
e^{-\alpha_n t_n} \mathbb{E}[[\overline{\mathbb{BP}}_n(t_n)] \to A,
\] (4.38)
where $A = (\nu - 1)/\alpha_n\nu \bar{\nu}$. Denote by $\varphi(s) = \int_0^\infty e^{-st} f_\xi(y) \, dy$, the Laplace transform of $f_\xi$, the density of the lifetime distribution $F_\xi$. Then
\[
\int_0^\infty e^{-st} \mathbb{E}[[\overline{\mathbb{BP}}_n(t)] \, dt = \frac{1 - \varphi(s)}{s(1 - \nu_n\varphi(s))}.
\] (4.39)

This equation follows directly from [20, Equation 16.1], with $m$ replaced by $\nu_n$ and is valid when the real part of $s$ satisfying $\text{Re}(s) > \alpha_n$, where $\alpha_n > 0$ is defined as the unique solution to $\nu_n\varphi(\alpha_n) = 1$ (compare (1.15)). From the inversion formula for Laplace transforms, we obtain
\[
\mathbb{E}[[\overline{\mathbb{BP}}_n(t)]] = \frac{1}{2\pi i} \int_\Gamma e^{st} \frac{1 - \varphi(s)}{s(1 - \nu_n\varphi(s))} \, ds,
\] (4.40)
where $\Gamma$ is the path $(c_0 - i\infty, c_0 + i\infty)$, with $c_0 > \alpha_n$. Since $\alpha_n \to \alpha$ and $\nu_n \to \nu > 1$ and $\varphi(s)$ is the Laplace transform of a probability density, the function $s(1 - \nu_n\varphi(s))$ has a simple zero
\[ s = \alpha_n, \text{ but no other zeros in a small strip } |s - \alpha_n| < \varepsilon, \text{ for some } \varepsilon > 0. \] It is then easy to conclude from Cauchy’s theorem, calculating the residue at \( s = \alpha_n \), that
\[
\mathbb{E}[|\mathbf{BP}_{n}(t_n)|] = e^{\alpha_n t_n} \frac{1 - \varphi'(-\alpha_n)}{\alpha_n \nu(1 - \nu \varphi'(-\alpha_n))} (1 + O(e^{-\varepsilon t_n}))
\]
\[ = A_n e^{\alpha_n t_n} (1 + O(e^{-\varepsilon t_n})), \quad (4.41)\]
where
\[
A_n = \frac{\nu_n - 1}{\alpha_n \nu_n^2 \int_0^\infty e^{-\alpha_n y} f_\xi(y) dy} = \frac{\nu_n - 1}{\alpha_n \nu_n \nu_n}.
\]
Since \( A_n \to A \), the claim \((4.38)\) follows.

For the second statement in Proposition 4.1(a) for the \( n \)-dependent CTBP, we replace the inequality in \((4.7)\) by the equivalent \( n \)-dependent statement, uniformly in \( k \geq 1 \),
\[
1 - \prod_{j=1}^{k} \frac{\nu_j}{\nu_n} \leq (\log(1/\eta_n))^{-1} \mathbb{E}[X_n \log(X_n/K_n)].
\]
\[ (4.43)\]
Since \( \lim_{n \to \infty} \mathbb{E}[X_n \log(X_n/K_n)] = 0 \), as \( n \to \infty \), the statement follows as in \((4.10)\).

For the \( n \)-dependent case of Proposition 4.1(b), we need to show that for all \( n \geq 1 \) and uniformly in \( t \),
\[
e^{-2\alpha_n t \mathbb{E}[|\mathbf{BP}_{n}^{(n)}(t)|^2] \leq CK_n,
\]
for some constant \( C \), and where \( m_j = K_n \eta_n^{-j} \). Copying the derivation which leads to \((4.16)\), we obtain
\[
\mathbb{E}[|\mathbf{BP}_{n}^{(n)}|^2] = \sum_{j=1}^{\infty} f_j^{(n)} \left( \mathbb{E}[|\mathbf{BP}_{n}^{(n)}|] \right)^2 * Q_n^2,
\]
where
\[
e_j^{(n)} = \frac{\eta_n \mathbb{E}[(X_n \wedge m_j)^2]}{\nu_n}, \quad f_j^{(n)} = \frac{\eta_n \mathbb{E}[(X_n \wedge m_j)]}{\nu_n},
\]
and
\[
\tilde{F}_n \xi(t) = \nu_n \int_0^t e^{-\alpha_n y} dF_\xi(y), \quad Q_n(t) = \eta_n^{-1} \nu_n \int_0^t e^{-2\alpha_n y} dF_\xi(y).
\]

From the proof of Lemma 4.3, we readily obtain that
\[
\sum_{j=1}^{\infty} f_j^{(n)} \left( \mathbb{E}[|\mathbf{BP}_{n}^{(n)}|] \right)^2 \leq \sum_{j=1}^{\infty} m_j^2 \mathbb{E}(X_n > m_j) \eta_n^2 + \sum_{j=1}^{\infty} \mathbb{E}[(X_n^2(1 \wedge m_j))] \eta_n^2 \leq \frac{2K_n \nu_n}{1 - \eta_n}. \quad (4.48)
\]
Since, \( \nu_n \to \nu \) and \( \eta_n \to \eta \), as \( n \to \infty \), we find, by combining \((4.45)\) and \((4.48)\), that given \( \varepsilon > 0 \), there is an \( n_0 \) so that for \( n > n_0 \), and uniformly in \( t \),
\[
e^{-2\alpha_n t \mathbb{E}[|\mathbf{BP}_{n}^{(n)}(t)|^2] \leq \frac{2K_n (\nu + \varepsilon) (A^2 + \varepsilon)}{1 - \eta - \varepsilon} \leq CK_n.
\]
\[ (4.49)\]
By enlarging the constant \( C \) we see that \((4.44)\) holds for all \( n \geq 1 \) and uniformly in \( t \).

Finally, we will give the proof of Proposition 4.1(c) for the \( n \)-dependent CTBP. We denote by \( |\mathbf{BP}_{n,j}(t, t + s)| \) the number of individuals in generation \( j \) having residual lifetime at most \( s \) at time \( t \) of the CTBP with offspring given by \( X_n \). Then, we obtain, similarly as in \((4.32)\),
\[
\mathbb{E}[|\mathbf{BP}_{n,j}(t, t + s)|] = \int_0^t \mathbb{E}[|\mathbf{BP}_{n}(t - y, t + s - y)|] dF_{n,\xi}^{(k + 1)}(y).
\]
\[ (4.50)\]
The expectation \( \mathbb{E}[|\mathbf{BP}_{n}(t, t + s)|] \) satisfies the renewal equation
\[
\mathbb{E}[|\mathbf{BP}_{n}(t, t + s)|] = F_\xi(t + s) - F_\xi(t) + \nu_n \int_0^t \mathbb{E}[|\mathbf{BP}_{n}(t - y, t + s - y)|] dF_\xi(y).
\]
\[ (4.51)\]
For $s > 0$ fixed, we denote by
\[ \tilde{K}_n(v, s) = \int_0^\infty e^{-vt} \mathbb{E}[|\mathcal{B}_n[t, t + s]|] \, dt, \quad \hat{f}(v, s) = \int_0^\infty e^{-vt} [F_\xi(t + s) - F_\xi(t)] \, dt, \]
the Laplace transforms of $\mathbb{E}[|\mathcal{B}_n[t, t + s]|]$ and $[F_\xi(t + s) - F_\xi(t)]$, respectively. Then (4.51) yields $\tilde{K}_n(v, s) = \hat{f}(v, s)/(1 - \nu_n \varphi(v))$. From the inversion theorem for Laplace transforms we obtain (compare (4.40)),
\[ \mathbb{E}[|\mathcal{B}_n[t, t + s]|] = \frac{1}{2\pi i} \int_{\Gamma} e^{vt} \hat{f}(v, s) \frac{dv}{1 - \nu_n \varphi(v)}, \]
where $\Gamma$ is the same path as in (4.40), so that from the theory of residues, for some $\varepsilon > 0$,
\[ \mathbb{E}[|\mathcal{B}_n[t_n, t_n + s]|] = \frac{e^{\alpha_\nu_\varepsilon t_n} \hat{f}(\alpha_\nu_\varepsilon, \varepsilon)}{-\nu_\varepsilon \varphi'(\alpha_\varepsilon)} (1 + O(e^{-\varepsilon t_n})) = e^{\alpha_\nu_\varepsilon t_n} A_n F_{n, R}(s) \left(1 + O(e^{-\varepsilon t_n})\right), \]
with $A_n$ defined in (4.42) and with
\[ F_{n, R}(s) = \frac{\alpha_n \nu_n}{\nu_n - 1} \int_0^\infty e^{-\alpha_n y} [F_\xi(y + s) - F_\xi(y)] \, dy. \]
Since $A_n \to A$ and $F_{n, R}(s) \to F_R(s)$ for $n \to \infty$, we obtain that, for any sequence $t_n \to \infty$,
\[ \lim_{n \to \infty} \mathbb{E}[|\mathcal{B}_n[t_n, t_n + s]|] = \lim_{n \to \infty} e^{-\alpha_\nu_\varepsilon t_n} \mathbb{E}[|\mathcal{B}_n[t_n, t_n + s]|] = AF_R(s). \]
The $n$-dependent definition $k_n(t_n, x)$ yields that $m = k_n(t_n, x) \to \infty$ implies $t_n \sim m \nu_\varepsilon - x \sigma / m$.

5. Bounds on the coupling: Proof of Proposition 2.2

5.1. Some simple lemmas concerning miscouplings. In (2.26), we have coupled the forward degrees in the SWT $(Y^{(a)}_k)_{k \geq 1}$, as well as the (possibly) reduced forward degrees $(X^{(a)}_k)_{k \geq 1}$, to an i.i.d. sequence $(B^{(a)}_k)_{k \geq 1}$ with distribution equal to that of $D_n^* - 1$ given in (2.5).

We next investigate some simple consequences of this coupling. For this, it will be useful to note that when $D_n$, having distribution function $F_n$ in (1.2), satisfies Condition 1.1(c), the maximal degree $\Delta_n = \max_{i \leq n} d_i$ satisfies
\[ \Delta_n = o(\sqrt{n \log n}). \]
Indeed, suppose that $\Delta_n \geq \varepsilon \sqrt{n \log n}$. Then, pick $K_n = n^{1/4}$ to obtain that
\[ \mathbb{E}[D_n^2 \log (D_n/K_n)_+] = \frac{1}{n} \sum_{k=1}^n d_k^2 \log (d_k/n^{1/4}) \geq \frac{\Delta_n^2}{n} \log (\Delta_n/n^{1/4}) \geq n^{-1}(\varepsilon \sqrt{n \log n})^2 \log (n^{1/4}/(\log n)^{1/2}) \geq \varepsilon^2/8. \]
This is in contradiction to Condition 1.1(c), so we conclude that (5.1) holds.

On $(\Omega, \mathcal{F}, \mathbb{P})$ we define the sigma-algebra $\mathcal{G}_k$ by
\[ \mathcal{G}_k = \sigma(d_{u_1}, d_{u_2}, \tau_j, X^{(a)}_j, Y^{(a)}_j, (B^{(a)}_{r_i})_{i \leq j, j \leq k}). \]
In the following lemma, we investigate the conditional probability of $Y^{(a)}_k \neq B^{(a)}_{r_{k-1}+1}$ given $\mathcal{G}_{k-1}$.

In its statement, we recall the definition of $S^{(a)}_k$ in (2.27).
Lemma 5.1 (Mischief of forward degree). Assume that Condition 1.1(c) holds. For all $k \leq m_n$, and assuming that $m_n \leq \sqrt{n \log n}$,

$$
\mathbb{P}(Y_k^{(n)} \neq B_{r_{k-1}+1}^{(n)} \mid \mathcal{G}_{k-1}) \leq \frac{1}{\ell_n(1-\alpha)} \left( S_0^{(n)} + \sum_{s=1}^{k-1} (Y_s^{(n)} + 1) \right) = o_p(1).
$$

(5.4)

Proof. We have that $Y_k^{(n)} \neq B_{r_{k-1}+1}^{(n)}$ precisely when we pair the half-edge $y_{r_{k-1}}^{(n)}$ to a half-edge of a previously chosen vertex. Now let $V_{\ell_0}, \ldots, V_{\ell_{k-2}}$ be the previously chosen vertices and let $Y_s^{(n)} = B_{r_s}^{(n)}$, for $s \leq k-1$, be the forward degree of vertex $V_{\ell_{s-1}}$, $s \leq k-1$. Then the total number of half-edges incident to chosen vertices is at most

$$
S_0^{(n)} + \sum_{s=1}^{k-1} (Y_s^{(n)} + 1).
$$

By (5.1), $\Delta_n = o(\sqrt{n / \log n})$, so that

$$
S_0^{(n)} + \sum_{s=1}^{k-1} (Y_s^{(n)} + 1) \leq (k+1) \Delta_n \leq (m_n + 1) \Delta_n = o(n).
$$

(5.5)

From (5.5), it is clear that we draw each time from at least $\ell_n - o(n) = \ell_n(1-\alpha)$ half-edges. This shows (5.4).

\[ \square \]

Lemma 5.2 (Probability of drawing at least one alive half-edge). Assume that Condition 1.1(c) holds. For all $k \leq m_n$, and assuming that $m_n \leq \sqrt{n \log n}$,

$$
\mathbb{P}(X_k^{(n)} < Y_k^{(n)} \mid \mathcal{G}_{k-1}) \leq \frac{\mathbb{E}[Y_k^{(n)} \mid \mathcal{G}_{k-1}]}{\ell_n(1-\alpha)} \left( S_0^{(n)} + \sum_{s=1}^{k-1} Y_s^{(n)} \right).
$$

(5.6)

Proof. Recall the definition of $S_0^{(n)}$ in (2.27). We have that $X_k^{(n)} < Y_k^{(n)}$ when we pair at least one of the $Y_k^{(n)}$ half-edges to a half-edge incident to \{U_1, U_2, V_{\ell_0}, \ldots, V_{\ell_{k-2}}\}. Since there are precisely $Y_k^{(n)}$ half-edges that need to be paired, and the number of half-edges incident to \{U_1, U_2, V_{\ell_0}, \ldots, V_{\ell_{k-2}}\}, given $\mathcal{G}_{k-1}$, equals $S_0^{(n)}$ for all $k \leq m_n$ and

$$
\mathbb{P}(X_k^{(n)} < Y_k^{(n)} \mid \mathcal{G}_{k-1}, Y_k^{(n)}) \leq \frac{Y_k^{(n)} \cdot S_0^{(n)}}{\ell_n - \sum_{s=1}^{k-1} (Y_s^{(n)} - 1) - S_0^{(n)} - 1}.
$$

(5.7)

Clearly, $S_0^{(n)} \leq S_0^{(n)} + \sum_{s=1}^{k-1} Y_s^{(n)}$. Consequently we obtain (5.6) from the tower-property for conditional expectations.

\[ \square \]

5.2. Proof of Proposition 2.2(a). The i.i.d. sequences $(B_i^{(n)})_{i \geq 1}$ and $(B_i)_{i \geq 1}$ have probability mass functions $(g_k^{(n)})_{k \geq 0}$ and $(g_k)_{k \geq 0}$ given in (2.4) and (2.5), respectively. Since $(g_k^{(n)})_{k \geq 0}$ and $(g_k)_{k \geq 0}$ are discrete distributions and since by Condition 1.1, the distribution $(g_k^{(n)})_{k \geq 1}$ converges as $n \to \infty$ in distribution to $(g_k)_{k \geq 1}$, it follows that

$$
d_{TV}(B_1^{(n)}, B_1) = \frac{1}{2} \sum_{k=0}^{\infty} |g_k - g_k^{(n)}| \to 0
$$

(5.8)

where $d_{TV}$ denotes the total variation distance, see for instance [39, Theorem 6.1].

Take $s_n \to \infty$ such that

$$
e^{2\alpha s_n} d_{TV}(B_1^{(n)}, B_1) \to 0.
$$

(5.9)

According to (1.20), and with $i \in \{1, 2\}$, we then obtain

$$
e^{-\alpha s_n} |\mathbb{B}^{(i)}(s_n)| \xrightarrow{a.s.} \mathbb{W}^{(i)},
$$

(5.10)

where $\mathbb{W}^{(i)}$ are two independent copies of $\mathbb{W}$. Since $\mathbb{P}(\mathbb{W}^{(i)} < \infty) = 1$ and $e^{2\alpha s_n} \to \infty$, we conclude that $|\mathbb{B}^{(i)}(s_n)| \leq k_n$, whp, if we take $k_n = [e^{2\alpha s_n}]$. If this $k_n$ does not satisfy $k_n = o(\sqrt{n})$, then we lower $s_n$ so that the corresponding value of $k_n = [e^{2\alpha s_n}]$ does satisfy $k_n = o(\sqrt{n})$. 

Recall the definition of $G_k$ in (5.3). By Boole’s inequality,
\[
\Pr(X_k^{(n)} \neq B_k^{(n)} \mid G_{k-1}) \leq \Pr(X_k^{(n)} < Y_k^{(n)} \mid G_{k-1}) + \Pr(Y_k^{(n)} \neq B_k^{(n)} \mid G_{k-1}).
\] (5.11)

Using Lemmas 5.1–5.2, and by taking the expectation, a lower bound for the probability of all forward-degree-couplings being successful during the first $k_n = o(\sqrt{n})$ pairings is
\[
\Pr\left( \bigcap_{k=1}^{k_n} \{ X_k^{(n)} = B_k^{(n)} \} \right) = 1 - \Pr\left( \bigcup_{k=1}^{k_n} \{ X_k^{(n)} \neq B_k^{(n)} \} \right)
\] (5.12)
\[
\geq 1 - \frac{1}{\ell_n (1 - o(1))} \sum_{k=1}^{k_n} \mathbb{E}[S_0^{(n)}] + \sum_{s=1}^{k_n} \mathbb{E}[Y_s^{(n)} + 1] - \frac{1}{\ell_n (1 - o(1))} \sum_{k=1}^{k_n} \mathbb{E}[\mathbb{E}[Y_k^{(n)} \mid G_{k-1}] = S_0^{(n)} + \sum_{s=1}^{k_n} Y_s^{(n)}]}
\end{equation}
\[
\geq 1 - ck_n^2/n \to 1,
\]
where we rely on the inequality
\[
\mathbb{E}[Y_k^{(n)} \mid G_{k-1}] \leq \sum_{j \in [n]} \frac{d_j (d_j - 1)}{\ell_n - 2k_n \Delta_n} = \nu_n (1 + o(1)),
\] (5.13)
whenever $k_n \Delta_n = o(n)$, which follows from (5.1).

The lower bound (5.12) implies that, whp, the number of half-edges $(|AH(s)|)_{s \in [0,s_n]}$ is perfectly coupled to the number of (alive) individuals of the $n$-dependent CTBP $(|Al_n(s)|)_{s \in [0,s_n]}$, in turn, (5.9) shows that $(BP_n(s))_{s \leq s_n}$ is whp perfectly coupled to $(BP(s))_{s \leq s_n}$. This proves Proposition 2.2(a).

We close this section by investigating moments of the size-biased random variables $(Y_k^{(n)})_{k \geq 1}$, which play a crucial role in the remainder of the paper:

**Lemma 5.3** (Moments of size-biased samplings). Assume that Condition 1.1 (a-c) holds. For all $k \leq m_n$, and assuming that $m_n \leq \sqrt{n \log n}$, and for any $K_n \to \infty$ such that $K_n^2 = o(n/m_n)$,
\[
\mathbb{E}[Y_k^{(n)} \mathbb{1}_{\{Y_k^{(n)} \leq K_n\}} \mid G_{k-1}] = (1 + o_p(1)) \nu_n,
\] (5.14)
\[
\mathbb{E}[Y_k^{(n)} \mathbb{1}_{\{Y_k^{(n)} > K_n\}} \mid G_{k-1}] = o(1).
\] (5.15)

**Proof.** We use the upper bound
\[
\mathbb{E}[Y_k^{(n)} \mathbb{1}_{\{Y_k^{(n)} \geq a\}} \mid G_{k-1}] \leq \frac{1}{\ell_n (1 - o(1))} \sum_{l \in [n]} d_l (d_l - 1) \mathbb{1}_{\{d_l \geq a\}}.
\] (5.16)
where we again use that, since $m_n \leq \sqrt{n \log n}$,
\[
\ell_n - S_0^{(n)} - \sum_{j=1}^{k_n} Y_j^{(n)} \geq \ell_n - (m_n + 1) \Delta_n = \ell_n (1 - o(1)).
\] (5.17)

This provides the necessary upper bound in (5.14) by taking $a = 0$ and from the identity $\nu_n = \sum_{l \in [n]} d_l (d_l - 1)/\ell_n$. For (5.15), this also proves the necessary bound, since by Condition 1.1(c),
\[
\frac{1}{\ell_n} \sum_{l \in [n]} d_l (d_l - 1) \mathbb{1}_{\{d_l \geq K_n\}} = o(1).
\] (5.18)

For the lower bound in (5.14), we bound, instead,
\[
\mathbb{E}[Y_k^{(n)} \mathbb{1}_{\{Y_k^{(n)} \leq K_n\}} \mid G_{k-1}] \geq \frac{1}{\ell_n (1 - o(1))} \left[ \sum_{l \in [n]} d_l (d_l - 1) \mathbb{1}_{\{d_l \leq K_n\}} - \sum_{l \in [n]} d_l (d_l - 1) \mathbb{1}_{\{d_l \leq K_n\}} \mathbb{1}_{\{l \text{ is chosen}\}} \right].
\] (5.19)
where the event ‘l is chosen’ means that vertex l belongs to the set of already chosen vertices $U_1, U_2, V_{20}, \ldots, V_{s_{m_n-2}}$. The first term equals $\nu_n(1 + o(1))$. The second term is a.s. bounded by $m_nK_n^2/\ell_n = o(1)$, since $K_n^2 = o(n/m_n)$.

5.3. Completing the coupling: Proof of Proposition 2.2(b). In this section, we use Proposition 4.1 to prove Proposition 2.2(b). In order to bound the difference between BP(t) and SWT(t), we will introduce several events. Let $B_n, C_n, \varepsilon_n, \overline{m}_n, m_n$ denote sequences of real numbers for which $B_n, C_n \to \infty$ and $\varepsilon_n \to 0$ arbitrarily slowly, and $\overline{m}_n \gg \sqrt{n}, m_n \ll \sqrt{n}$. Later in this proof, we will formulate precisely how to choose these sequences.

Define the event $\mathcal{A}_n$ by

$$\mathcal{A}_n = \left\{ \bigcup_{s \in [0, t_n + B_n]} \text{SWT}(s) \triangle \text{BP}_n(s) \right\} < \varepsilon_n\sqrt{n},$$

(5.20)

where we recall that $\text{SWT}(s) \triangle \text{BP}_n(s)$ is the set of alive half-edges at time $s$ that are miscoupled, and where we recall further that an alive half-edge is miscoupled if the shortest-weight path from the root to the vertex incident to that half-edge uses at least one degree-miscoupled vertex. Similarly an alive individual is miscoupled if at least one of its ancestors is degree miscoupled. Note that when $\mathcal{A}_n$ holds, then $\left\{ \bigcup_{s \in [0, t]} \text{SWT}(s) \triangle \text{BP}_n(s) \right\} < \varepsilon_n\sqrt{n}$ for any $t \leq t_n + B_n$ by monotonicity in $t$ (see Definition (2.35)).

In terms of the above notation, Proposition 2.2(b) can be reformulated as

$$\mathbb{P}(\mathcal{A}_n^c \mid \mathcal{F}_{s_n}) = o(1).$$

(5.21)

Hence only a tiny fraction of the alive half-edges or individuals is miscoupled and the alive half-edges that are not miscoupled are connected to the root via a path containing only successfully coupled vertices.

In order to prove (5.21), we introduce the following events:

$$B_n = \{Y^{(\text{BP})}(t_n + B_n) \leq \overline{m}_n\} \cap \{Y^{(\text{SWT})}(t_n + B_n) \leq \overline{m}_n\}$$

$$\cap \{Y^{(\text{BP})}(t_n - B_n) \leq m_n\} \cap \{Y^{(\text{SWT})}(t_n - B_n) \leq m_n\},$$

(5.22)

$$C_n = \{\text{SWT}(|t|) = |\text{BP}_n(t)|, \forall t \leq t_n - B_n\},$$

(5.23)

$$D_n = \{\exists i \text{ such that } T_i \leq t_n + B_n, X_i^{(s)} \neq B_{i-1}^{(n)}, d_{V_{s+i}} \geq C_n\},$$

(5.24)

where

$$Y^{(\text{BP})}(t) = |\{v: v \in \text{BP}_n(s) \text{ for some } s \leq t\}|,$$

(5.25)

denotes the total number of individuals ever born into the BP_n before time $t$ and

$$Y^{(\text{SWT})}(t) = |\{v: v \in \text{AH}(s) \text{ for some } s \leq t\}|,$$

(5.26)

denotes the number of half-edges in the SWT that have ever been alive before time $t$. Informally, on $B_n$, the total number of half-edges in SWT and individuals in the CTBP are not too large. On $C_n$, there is no early degree-miscoupled vertex, while on $D_n$, there is no degree miscoupling involving a vertex that has high degree, until a late stage.

Obviously,

$$\mathbb{P}(\mathcal{A}_n^c \mid \mathcal{F}_{s_n}) \leq \mathbb{P}(B_n^c \mid \mathcal{F}_{s_n}) + \mathbb{P}(C_n^c \cap B_n \mid \mathcal{F}_{s_n}) + \mathbb{P}(D_n^c \cap B_n \cap C_n \mid \mathcal{F}_{s_n}) + \mathbb{P}(A_n^c \cap B_n \cap C_n \cap D_n \mid \mathcal{F}_{s_n}).$$

To bound conditional probabilities of the form $\mathbb{P}(\mathcal{E}^c \mid \mathcal{F}_{s_n})$ as appearing in (5.21), we note that it suffices to prove that $\mathbb{P}(\mathcal{E}^c) = o(1)$, since then, by the Markov inequality and for every $\varepsilon > 0$,

$$\mathbb{P}\left[ \mathbb{P}(\mathcal{E}^c \mid \mathcal{F}_{s_n}) \geq \varepsilon \right] \leq \mathbb{E}[\mathbb{P}(\mathcal{E}^c \mid \mathcal{F}_{s_n})]/\varepsilon = \mathbb{P}(\mathcal{E}^c)/\varepsilon = o(1).$$

(5.28)

Thus, we are left to prove that

$$\mathbb{P}(B_n^c) = o(1), \quad \mathbb{P}(C_n^c \cap B_n) = o(1), \quad \mathbb{P}(D_n^c \cap B_n \cap C_n) = o(1), \quad \mathbb{P}(A_n^c \cap B_n \cap C_n \cap D_n) = o(1).$$

(5.29)

We will do so in the above order.
Lemma 5.4 (Expected number of particles born). For all \( t \geq 0 \),
\[
\mathbb{E}[Y^{(BP)}(t)] = 2\left(1 - \frac{\mathbb{E}[D_n]F_\xi(t)}{\nu_n - 1}\right) + \frac{\nu_n}{\nu_n - 1}\mathbb{E}[||BP_n(t)||].
\] (5.30)

Moreover, when \( e^{\alpha_n(t_n + B_n)} = o(\ell_n) \) and \( e^{\alpha_n(t_n - B_n)} = o(\ell_n) \),
\[
\mathbb{P}(\mathcal{B}_n^c) = o(1).
\] (5.31)

\textbf{Proof.} Note that we grow two sets of alive half-edges and two BP’s, which explains the factor 2 in (5.30). As is well known, the expected number of descendants in generation \( k \) of a BP equals \( \nu^k_n \), where \( \nu_n \) denotes the mean offspring. Here, we deal with a delayed generation the mean number of offspring equals \( \mathbb{E}[D_n] \); the factor \( F_\xi^{(k)}(t) - F_\xi^{(k+1)}(t) \) represents the probability that an individual of generation \( k \) is alive at time \( t \). Together this yields
\[
\mathbb{E}[||BP_n(t)||] = \sum_{k=1}^{\infty} 2\mathbb{E}[D_n]\nu^k_n - [F_\xi^{(k)}(t) - F_\xi^{(k+1)}(t)], \quad \mathbb{E}[Y^{(BP)}(t)] = 2 + \sum_{k=1}^{\infty} 2\mathbb{E}[D_n]\nu^k_n - F_\xi^{(k)}(t).
\] (5.32)

It is not difficult to deduce (5.30) from the two identities above.

To bound \( \mathbb{P}(\mathcal{B}_n^c) \), we note that we have to bound events of the form \( \mathbb{P}(Y^{(BP)}(t) \geq m) \) and \( \mathbb{P}(Y^{(SWT)}(t) \geq m) \) for various choices of \( m \) and \( t \). We use the Markov inequality and (5.30) to bound
\[
\mathbb{P}(Y^{(BP)}(t) \geq m) \leq \mathbb{E}[Y^{(BP)}(t)]/m \leq \frac{\nu_n}{m(\nu_n - 1)}\mathbb{E}[||BP_n(t)||] + \frac{2}{m}.
\] (5.33)

According to (4.41), after conditioning on the offspring of the first individual, \( \mathbb{E}[||BP_n(t)||] = \mathbb{E}[D_n]A_n\ell_n(t_n + o(1)) \), so that, since \( \mathbb{E}[D_n] \to \mathbb{E}[D] \),
\[
\mathbb{P}(Y^{(BP)}(t) \geq m_n) = \Theta(e^{\alpha_n t_n}/m_n).
\] (5.34)

The conditions on \( t \) and \( m \) in Lemma 5.4 have been chosen precisely so that \( e^{\alpha_n(t_n - B_n)}/m_n \to 0 \), and \( e^{\alpha_n(t_n + B_n)/\ell_n} \to 0 \).

We continue with \( \mathbb{P}(Y^{(SWT)}(t) \geq m) \). We use the same steps as above, and start by computing
\[
\mathbb{E}[Y^{(SWT)}(t)] = 2 + 2\sum_{k=0}^{\infty} F_\xi^{(k)}(t)\mathbb{E}[P^*_k], \quad k \geq 1,
\] (5.35)

where \( P^*_0 = \ell_n/n \) and
\[
P^*_k = \sum_{|\pi|=k, \pi \subseteq CM_n(d)} (d_{\pi} - 1)/n, \quad k \geq 1,
\]
is the sum of the number of half-edges at the ends of paths of lengths \( k \) in \( CM_n(d) \), from a uniformly selected starting point. Following [26, Proof of Lemma 5.1], we find that
\[
\mathbb{E}[P^*_k] = \frac{1}{n} \sum_{v_0, \ldots, v_k} d_{v_0} \prod_{i=1}^{k} d_{v_i}(d_{v_i} - 1) \leq \mathbb{E}[D_n]\nu^k_n,
\] (5.36)

where the sum is taken over distinct vertices in \( [n] \). Note that our definition of \( \nu_n \) deviates from the one given in [26, (2.3)], which explains the difference between the right-hand side of (5.36) and the result in [26]. We obtain,
\[
\mathbb{E}[Y^{(SWT)}(t)] \leq 2 + 2\sum_{k=0}^{\infty} F_\xi^{(k)}(t)\mathbb{E}[D_n]\nu^k_n \leq 2\mathbb{E}[D_n] + \nu_n\mathbb{E}[Y^{(BP)}(t)],
\] (5.37)

and we can repeat our arguments for \( \mathbb{E}[Y^{(BP)}(t)] \).

\textbf{Lemma 5.5 (No early degree-miscoupling).} When \( m_n = o(\sqrt{n}) \), then
\[
\mathbb{P}(C_n^c \cap B_n) = o(1).
\] (5.38)

\textbf{Proof.} On \( B_n \), the inequality \( Y^{(SWT)}(t_n - B_n) \leq m_n \) holds. By (5.12), the probability that there exists a degree-miscoupling before the draw of the \( m_n \)th half-edge is \( o(1) \) when \( m_n = o(\sqrt{n}) \).
Lemma 5.6 (No late miscouplings of high degree). If $\overline{m}_n \leq \sqrt{n \log n}$, and $C_n$ satisfies
\begin{equation}
\frac{\overline{m}_n}{k} \sum d_i^2 \mathbb{1}_{\{d_i \geq C_n\}} = o(n),
\end{equation}
then
\begin{equation}
\mathbb{P}(D_n^c \cap B_n \cap C_n) = o(1).
\end{equation}

Proof. On $B_n$, we have that $Y^{(\text{SWT})}(t_n + B_n) \leq \overline{m}_n$, and hence for a degree-miscoupling, when $D_n^c$ holds, one of the vertices $i \in [n]$ with $d_i \geq C_n$ has to be chosen twice during the first $\overline{m}_n$ pairings. By Boole’s inequality and (5.39), an upper bound for this probability is
\begin{equation}
\overline{m}_n^2 \sum_{i \in [n]} \frac{d_i^2}{(\ell_n - o(n))^2} \mathbb{1}_{\{d_i \geq C_n\}} = \frac{\overline{m}_n^2}{(\ell_n - o(n))^2} \cdot \ell_n o(n) = o(1).
\end{equation}

Proposition 5.7 (Degree-miscoupled half-edges have small offspring). If $\overline{m}_n \leq \sqrt{n \log n}$ and $e^{2\alpha_n B_n} C_n \overline{m}_n^2 / \ell_n = o(\varepsilon \sqrt{n})$, then
\begin{equation}
\mathbb{P}(A_n^c \cap B_n \cap C_n \cap D_n) = o(1).
\end{equation}

Proof. We split the proof into the contribution of the degree-miscoupled vertices in $|\mathbb{B}P_n(t) \setminus \text{SWT}(t)|$ and those in $|\text{SWT}(t) \setminus \mathbb{B}P_n(t)|$, $t \leq t_n + B_n$.

A bound on $|\mathbb{B}P_n(t) \setminus \text{SWT}(t)|$. Recall that at time $T_k$, the vertex $V_{2k - 1}$ is degree-miscoupled when one of the equalities in (2.26) fails.

When $Y_{k}^{(o)} \neq B_{k-1}^{(o)}$, we can give an upper bound on the contribution to $\mathbb{B}P_n(t) \setminus \text{SWT}(t)$, $t \leq t_n + B_n$.

\begin{equation}
Y_{k}^{(\text{BP})}(t_n + B_n - T_k),
\end{equation}
where, for different $k \geq 1$, $(Y_{k}^{(\text{BP})}(t))_{t \geq 0}$ are independent CTBPs. On $C_n$, we have that $T_k \geq t_n - B_n$ so that $t_n + B_n - T_k \leq 2B_n$, while on $D_n$, each degree-miscoupling starts with a vertex with degree at most $C_n$. Therefore, from (4.41),
\begin{equation}
\mathbb{E}[Y_{k}^{(\text{BP})}(t_n + B_n - T_k) \mathbb{1}_{C_n \cap D_n}] \leq C_n A_n e^{2\alpha_n B_n} (1 + o(1)).
\end{equation}

On $B_n$, the expected number of miscoupling is at most $O(\overline{m}_n^2 / \ell_n)$, hence
\begin{equation}
\mathbb{E}
\left[
\sum_{\{k: T_k \leq t_n + B_n\}} Y_{k}^{(\text{BP})}(t_n + B_n - T_k) \mathbb{1}_{B_n \cap C_n \cap D_n}
\right] \leq O\left(\frac{\overline{m}_n^2}{\ell_n}\right) C_n e^{2\alpha_n B_n}.
\end{equation}

By assumption, the right-hand side is $o(\varepsilon \sqrt{n})$. Therefore, by the Markov inequality,
\begin{equation}
\mathbb{P}\left(\{\mathbb{B}P_n(s)_{s \in [0, t_n + B_n]} \setminus \text{SWT}(s)_{s \in [0, t_n + B_n]}\} \supseteq \varepsilon \sqrt{n} \cap B_n \cap C_n \cap D_n \cap \text{MISC}\right) = o(1),
\end{equation}
where the intersection with MISC indicates that we only deal with degree-miscouplings of the form $Y_{k}^{(o)} \neq B_{k-1}^{(o)}$.

When $Y_{k}^{(n)} \neq X_{k}^{(n)}$, a self-loop or cycle-creating event occurs and the two half-edges that form the last edge in the cycle are removed from $\text{SWT}(t)$, but they are kept in $\mathbb{B}P_n(t)$. In case of a removal of a collision edge, only one individual is kept in $\mathbb{B}P_n(t)$. Whether one or two individuals are kept in the $\mathbb{B}P_n(t)$ is of no consequence for the argument below.

Again, on the event $B_n \cap C_n$, the expected number of degree pairings is bounded by $O(\overline{m}_n^2 / \ell_n)$. Furthermore, on the event $B_n \cap C_n$, the expected offspring of the half-edges involved in cycle-creating events is at most
\begin{equation}
\nu_n \mathbb{E}[Y_{k}^{(\text{BP})}(2B_n)],
\end{equation}
where $(Y_{k}^{(\text{BP})}(t))_{t \geq 0}$ is the total number of individuals that have ever been alive in a CTBP where all individuals have i.i.d. offspring with law $(g_k^{(o)})_{k \geq 0}$. Indeed, we have no information about the remaining lifetime of the half-edge involved in an event that is caused by $Y_{k}^{(n)} \neq X_{k}^{(n)}$. As a result,
rather than waiting for the residual life-time to be completed, we *instantaneously* take as offspring an i.i.d. draw from \((g_k^{(n)})_{k \geq 0}\), and start the various \(BP_n(t)\) from there (on the average there are \(\nu_n\) of these \(BP_n\)). The total number of individuals ever alive only increases by this change. On the event \(\mathcal{D}_n\), we have that \(\mathbb{E}[Y^{(BP)}(2B_n)] \leq C_n A_n e^{2\alpha_n B_n/\ell_n} + o(1)\). By assumption, \(m_n^2 C_n A_n e^{2\alpha_n B_n/\ell_n} = o(\varepsilon_n \sqrt{n})\). Therefore, the total contribution to \(|BP_n(t) \setminus SWT(t)|, t \leq t_n + B_n\), due to degree miscouplings of the kind \(Y^{(n)}_{k} \neq X^{(n)}_{k}\) events is \(o(\varepsilon_n \sqrt{n})\), as required.

A bound on \(|SWT(t) \setminus BP_n(t)|\). By construction, the number of miscoupled half-edges in \(SWT(s)_{s \in [0,t]}\) at any time \(t\) is bounded from above by

\[
\sum_{j=1}^{\text{MIS}(t)} Y^{(SWT)}_j(t - T_j),
\]

where \(\text{MIS}(t)\) denotes the number of degree-miscoupled vertices and \(Y^{(SWT)}_j(t - T_j)\) is the number of half-edges reached by the liquid during \([T_j, t]\), and which are in the tree with root \(V_{2j-1}\). On the event \(\mathcal{C}_n\), we have that \(T_1 \geq t_n - B_n\). Therefore, on the event \(\mathcal{C}_n\),

\[
|SWT(t)_{t \in [0,t_n + B_n]} \setminus BP_n(t)_{t \in [0,t_n + B_n]}| \leq \sum_{j=1}^{\text{MIS}(t_n + B_n)} Y^{(SWT)}_j(2B_n).
\]

By the Markov inequality,

\[
P\left(\{SWT(t)_{t \in [0,t_n + B_n]} \setminus BP_n(t)_{t \in [0,t_n + B_n]}| \geq \varepsilon_n \sqrt{n}\} \cap \mathcal{B}_n \cap \mathcal{C}_n \cap \mathcal{D}_n\right) \\
\leq (\varepsilon_n \sqrt{n})^{-1} \mathbb{E}\left[1_{\mathcal{B}_n \cap \mathcal{D}_n} \sum_{j=1}^{\text{MIS}(t_n + B_n)} Y^{(SWT)}_j(2B_n)\right].
\]

We rewrite

\[
\mathbb{E}\left[1_{\mathcal{B}_n \cap \mathcal{D}_n} \sum_{j=1}^{\text{MIS}(t_n + B_n)} Y^{(SWT)}_j(2B_n)\right] = (1 + o(1)) \sum_{j \in [n]} \mathbb{P}(j \text{ is degree-miscoupled, } \mathcal{B}_n \cap \mathcal{D}_n) \mathbb{E}[Y^{(SWT)}(2B_n)]
\]

\[
\leq (1 + o(1)) \sum_{j \in [n]} \left(\frac{d_j m_n}{\ell_n}\right)^2 \mathbb{1}\{d_j < \mathcal{C}_n\} \mathbb{E}[Y^{(SWT)}(2B_n)],
\]

where we use that, upon degree-miscoupling of vertex \(j\), we redraw a vertex from the size-biased distribution, for which the number of half-edges found before time \(2B_n\) is equal to \(\mathbb{E}[Y^{(SWT)}(2B_n)](1 + o(1))\) since \(m_n \leq \sqrt{n \log n}\) and \(B_n\) occurs. Since \(\mathbb{E}[Y^{(SWT)}(t)] \leq 2\mathbb{E}[D_n] + \nu_n \mathbb{E}[Y^{(BP)}(t)]\), we obtain that

\[
\mathbb{E}[Y^{(SWT)}(2B_n)] \leq \nu_n A_n e^{2\alpha_n B_n}(1 + o(1)).
\]

Therefore, we arrive at

\[
\mathbb{E}\left[1_{\mathcal{B}_n \cap \mathcal{D}_n} \sum_{j=1}^{\text{MIS}(t_n + B_n)} Y^{(SWT)}_j(2B_n)\right] \leq \nu_n A_n e^{2\alpha_n B_n}(1 + o(1)) \sum_{j \in [n]} \left(\frac{d_j m_n}{\ell_n}\right)^2 \mathbb{1}\{d_j < \mathcal{C}_n\}.
\]

Bounding \(\sum_{j \in [n]} d_j^2 \mathbb{1}\{d_j < \mathcal{C}_n\} \leq C_n \ell_n\), the right-hand side of (5.53) is bounded by \(\nu_n A_n e^{2\alpha_n B_n}(1 + o(1))C_n m_n^2/\ell_n = o(\varepsilon_n \sqrt{n})\). Combining this with (5.50) proves that \(|SWT(t)_{t \in [t_n + B_n]} \setminus BP_n(t)_{t \in [t_n + B_n]}| = o(\varepsilon_n \sqrt{n})\) on \(\{\mathcal{B}_n \cap \mathcal{C}_n \cap \mathcal{D}_n\}\).

**Proof of Proposition 2.2 (b).** Take

\[
m_n = \sqrt{n}/(\log \log n)^{\alpha/2}, \quad m_n = \sqrt{n}(\log n)^{1/4},
\]

(5.54)
and
\[ B_n = \log \log \log n, \quad C_n = n^{1/4}, \quad \varepsilon_n = 1/\log n. \]
By Condition 1.1(c) applied with \( K_n = \sqrt{C_n}/e \), and using that \( \log C_n \leq \log(eD_n/\sqrt{C_n}) \) when \( D_n \geq C_n \),
\[ \frac{1}{n} \sum_{i \in [n]} d_i^2 1\{d_i \geq C_n\} = \mathbb{E}[D_n^2 1\{D_n \geq C_n\}] \leq \mathbb{E}\left[\frac{D_n^2 \log(e \cdot D_n/\sqrt{C_n})^+}{\log \sqrt{C_n}}\right] = o((\log n)^{-1}), \]
which verifies (5.39). All other conditions in Lemmas 5.4–5.6 and Proposition 5.7 are straightforward. Therefore, (5.21) follows, which completes the proof of Proposition 2.2(b).

6. Height CLT and stable age: Proof of Proposition 2.3

We first prove Proposition 2.3(a). Throughout this proof, we abbreviate \( k_n = k_n(t, x) \) as in (2.42). The proof contains several key steps:

**Reduction to a single BP.** We start by showing that, in order for Proposition 2.3(a) to hold, it suffices to prove that for \( j \in \{1, 2\} \), \( x, t \in \mathbb{R} \) and \( s > 0 \), such that \( t + s < B_n \), conditionally on \( \mathcal{F}_s \), and on \( \mathcal{W}_{\mathcal{F}_s}^{(1)}, \mathcal{W}_{\mathcal{F}_s}^{(2)} > 0 \),
\[ e^{-\alpha t n} |\mathcal{B}_{n,k}^{(j)}[\tilde{t}_n + t, \tilde{t}_n + t + s]| \xrightarrow{p} e^{\alpha t} \Phi(x) F_k(s) \sqrt{\mathcal{W}^{(j)}/\mathcal{W}^{(3-j)}}, \]
where we use (2.37) in Proposition 2.2(a) to see that \( \sqrt{\mathcal{W}^{(j)}/\mathcal{W}^{(3-j)}} \in [\varepsilon, 1/\varepsilon] \) whp. Indeed, by Proposition 2.2(b) and the fact that \( e^{-\alpha t n} = \Theta_p(n^{-1/2}) \), (6.1) implies that for \( t + s < B_n \),
\[ e^{-\alpha t n} |\mathcal{S}_{\mathcal{W}^{(j)}}[\tilde{t}_n + t, \tilde{t}_n + t + s]| = e^{-\alpha t n} |\mathcal{B}_{n,k}^{(j)}[\tilde{t}_n + t, \tilde{t}_n + t + s]| + e^{-\alpha t n} o_2(\varepsilon_n \sqrt{n}) \]
\[ \xrightarrow{p} e^{\alpha t} \Phi(x) F_k(s) \sqrt{\mathcal{W}^{(j)}/\mathcal{W}^{(3-j)}}, \]
which proves Proposition 2.3(a) by the independence of the two CTBPs involved.

**Using the branching property.** To prove (6.1), we note that \( (\mathcal{B}_{n,k}^{(j)}(s))_{s \geq s_n} \) is the collection of alive individuals in the different generations of a CTBP, starting from the alive particles in \( (\mathcal{B}_{n,k}^{(j)}(s_n)) \). Then, conditionally on \( \mathcal{F}_s \),
\[ |\mathcal{B}_{n,k}^{(j)}[\tilde{t}_n + t, \tilde{t}_n + t + s]| = \sum_{i \in \mathcal{B}_{n,k}^{(j)}(s_n)} \sum_{k=1}^{k_n - G_k^{(j)}} |\mathcal{B}_{n,k}^{(j)}[\tilde{t}_n + t - s_n - R_i, \tilde{t}_n + t + s - s_n - R_i]|, \]
where \( G_k^{(j)} \) is the generation of individual \( i \in \mathcal{B}_{n,k}^{(j)}(s_n) \), while \( R_i = R_i(s_n) \) is its remaining lifetime at time \( s_n \), and \( (\mathcal{B}_{n,k}^{(j)}(t))_{t \geq 0} \) are i.i.d. CTBPs for different \( i \), for which the offspring for each individual has distribution \( (g_k^{(j)})_{k \geq 0} \), and where the branching process starts with one individual that dies immediately and has offspring distributed as \( (g_k^{(i)})_{k \geq 0} \).

**Truncating the branching process.** We continue by proving that we can truncate the branching process at the expense of an error term that converges to zero in probability. We let \( \mathcal{B}_{n,k}^{(i,j,m)} \) denote the branching process \( \mathcal{B}_{n,k}^{(i)} \) obtained by truncating particles in generation \( l \) (measured from the root \( i \)) by \( m = K_n \eta_p^{-1} \). We take \( K_n \to \infty \) such that \( K_n e^{-\alpha t n s_n} = o(1) \). We first show that, as \( t_n \to \infty \), we can replace \( e^{-\alpha t n} |\mathcal{B}_{n,k}^{(i,j)}[\tilde{t}_n + t, \tilde{t}_n + s]| \) by \( e^{-\alpha t n} |\mathcal{B}_{n,k}^{(i,j,m)}[\tilde{t}_n, \tilde{t}_n + s]| \), at the expense of a \( o_p(1) \)-term. Indeed, with
\[ |\mathcal{B}_{n,k}^{(i,j)}(t)| = \sum_{k=1}^{\infty} |\mathcal{B}_{n,k}^{(i,j)}(t)|, \quad |\mathcal{B}_{n,k}^{(i,j,m)}(t)| = \sum_{k=1}^{\infty} |\mathcal{B}_{n,k}^{(i,j,m)}(t)|, \]
by the \( n \)-dependent version of Proposition 4.1(a) in Proposition 4.1(d), which we apply to each of the individuals born at time \( s_n + R_i \), and for each sequence \( u_n \to \infty \), we have that
\[ e^{-\alpha t n} \mathbb{E}\left[|\mathcal{B}_{n,k}^{(i,j)}(u_n)| - |\mathcal{B}_{n,k}^{(i,j,m)}(u_n)|\right] \leq e^{-\alpha t n} \mathbb{E}\left[|\mathcal{B}_{n,k}^{(i,j)}(u_n)| - |\mathcal{B}_{n,k}^{(i,j,m)}(u_n)|\right] = o(1). \]
Therefore, using that the law of \((\text{BP}_{n,i}^{(j,\tilde{t})})_{i \leq 0, k} \mid t \geq 0\) only depends on \(F_{S_n}\) through \(R_{ij}, \tilde{t}_{ij}\),

\[
    e^{-\alpha_n t_n} \sum_{i \in \text{BP}_{n,i}^{(j,\tilde{t})}(s_n)} \sum_{k=1}^{k_n-G^j_{(i)}} \mathbb{E} \left[ |\text{BP}_{n,k}^{(i,j)}(\tilde{t}_n + t - s_n - R_i)| - |\text{BP}_{n,k}^{(i,j,\tilde{t})}(\tilde{t}_n + t - s_n - R_i)\right] | F_{S_n} \right] 
\]

\[
    \leq e^{-\alpha_n t_n} \sum_{i \in \text{BP}_{n,i}^{(j,\tilde{t})}(s_n)} \mathbb{E} \left[ |\text{BP}_{n,k}^{(i,j)}(\tilde{t}_n + t - s_n - R_i)| - |\text{BP}_{n,k}^{(i,j,\tilde{t})}(\tilde{t}_n + t - s_n - R_i)\right] | R_i, \tilde{t}_n \right] 
\]

\[= o(1) \sum_{i \in \text{BP}_{n,i}^{(j,\tilde{t})}(s_n)} e^{\alpha_n(\tilde{t}_n - t_n + t - s_n - R_i)} = o_p(1) e^{-\alpha_{s_n}} \sum_{i \in \text{BP}_{n,i}^{(j,\tilde{t})}(s_n)} e^{-\alpha R_i}, \quad (6.5)
\]

since the random variable \(|\tilde{t}_n - t_n|\) is tight, and assuming that \(s_n \to \infty\) so slowly that \(s_n|\alpha_n - \alpha| = o(1)\). Since \(R_i \geq 0\),

\[
e^{-\alpha_{s_n}} \sum_{i \in \text{BP}_{n,i}^{(j,\tilde{t})}(s_n)} e^{-\alpha R_i} \leq e^{-\alpha_{s_n}|\text{BP}_{n,i}^{(j,\tilde{t})}(s_n)|| \frac{d}{d} \tilde{W}(j) = o_p(1), \quad (6.6)
\]

by the ‘perfect’ coupling between \(\text{BP}_n\) and \(\text{BP}\) at time \(s_n\) stated in Proposition 2.2(a), and using that (see (1.20)),

\[
e^{-\alpha_{s_n}|\text{BP}_{n,i}^{(j,\tilde{t})}(s_n)|| \frac{d}{d} \tilde{W}(j) = o_p(1). \quad (6.7)
\]

We conclude that

\[
e^{-\alpha_n t_n} |\text{BP}_{n,i}^{(j,\tilde{t})}(\tilde{t}_n + t, t, \tilde{t}_n + t + s)| \left(\tilde{t}_n + t - s_n - R_i, \tilde{t}_n + t + s - s_n - R_i\right) + o_p(1). \quad (6.8)
\]

**A conditional second moment method: expectation.** We next use a conditional second moment estimate on the sum on the right-hand side of (6.8), conditionally on \(F_{S_n}\). By the \(n\)-dependent version of Proposition 4.1(c) in Proposition 4.1(d), \(t_n \to \infty\), and for each \(i \in \text{BP}_{n,i}^{(j,\tilde{t})}(s_n)\),

\[
e^{-\alpha_n t_n} \mathbb{E} \left[ |\text{BP}_{n,i}^{(j,\tilde{t})}(\tilde{t}_n + t, t, \tilde{t}_n + s)| \right] \to A\Phi(x) F_R(s). \quad (6.9)
\]

Observe that also \(m = k_n - k_n \to \infty\), with \(k_n = o(\sqrt{\log n})\), implies \(t_n \sim m \tilde{\nu}_n - x \tilde{\alpha} \sqrt{m}\), so that we can conclude from (4.56) that (6.9) also holds with \(k_n\) replaced by \(k_n - \tilde{k}_n\), as long as \(k_n = o(\sqrt{\log n})\). As a result, when \(\tilde{t}_n + t - s_n - R_i \to \infty\) and \(k_n = o(\sqrt{\log n})\) and for each \(i\),

\[
e^{-\alpha_n(\tilde{t}_n + t - s_n - R_i)} \mathbb{E} \left[ |\text{BP}_{n,i}^{(j,\tilde{t})}(\tilde{t}_n + t - s_n - R_i, \tilde{t}_n + t + s - s_n - R_i)| \left(\tilde{t}_n + t - s_n - R_i, \tilde{t}_n + t + s - s_n - R_i\right) + o_p(1). \quad (6.10)
\]

Further, we use the general theory of vertex characteristics in [23, Theorem 6.10.1] to conclude that

\[
\sum_{i \in \text{BP}_{n,i}^{(j,\tilde{t})}(s_n)} e^{-\alpha_n(s_n + R_i)} \xrightarrow{p} \tilde{W}(j)/A. \quad (6.11)
\]

Indeed, consider \(Z(t) = \sum_{i \in \text{BP}_{n,i}^{(j,\tilde{t})}(s_n)} e^{-\alpha_n R_i} = \sum_{i \in \text{BP}_{n,i}^{(j,\tilde{t})}(s_n)} 1[\tilde{t}_n \leq t \leq \tilde{t}_n + \xi_i] e^{-\alpha(\xi_i + \tilde{\tau}_i - t)}\), where the second sum is taken over all individuals and where \(\tilde{\tau}_i, \xi_i\) are the birthtime and lifetime of individual \(i\), respectively. Then with the terminology of [23, Section 6.9], \(Z(t) = Z^{\chi}(t) = \sum_{i \in \text{BP}(t)} \chi_i(t - \tilde{\tau}_i)\), where the random characteristic \(\chi_i\) of individual \(i\) is defined by

\[
\chi_i(t) = 1[0,\xi_i]\{t\} e^{-\alpha(\xi_i - t)}. \quad (6.12)
\]

According to the aforementioned [23, Theorem 6.10.1],

\[
e^{-\alpha t} Z(t) \to e_{\tilde{c}} \tilde{W}(k) \to k. \quad (6.13)
\]
where \( c_g = \int_0^\infty e^{-\alpha u} \mathbb{E}[\chi(u)] \, du / \int_0^\infty e^{-\alpha u} \, du \), \( k(\infty) = \int_0^\infty e^{-\alpha u} (1 - F_\xi(u)) \, du / \int_0^\infty e^{-\alpha u} \, du \) and where \( \mu(t) = \nu F_\xi(t) \). This yields \( c_g = 1/\nu \), and \( k(\infty) = (\nu - 1)/(\alpha^2 \nu) \), so that \( c_g/k(\infty) = 1/4 \).

The whp ‘perfect’ coupling between \((\text{BP}_n(s))_{s \leq s_n}\) with \((\text{BP}(s))_{s \leq s_n}\) stated in Proposition 2.2(a) and using that we may take \( s_n \to \infty \) so slowly that \( s_n(\alpha - \alpha_n) = o(1) \) implies (6.11).

This yields that, conditionally on \( F_{s_n} \), we next bound, conditionally on \( W_{s_n}^{(j)} \) \( W_{s_n}^{(j')} \), and where

\[
W_{s_n}^{(j)}(x) = \mathbb{E}
\]

\[
\sum_{i \in \text{BP}_n^{(j)}(s_n)} |\text{BP}_n^{(i,j,m)}(\bar{t}_n + t - s_n - R_i, \bar{t}_n + t + s - s_n - R_i)\rangle | \mathcal{F}_{s_n}
\]

\[
= \mathbb{E}
\]

\[
\sum_{i \in \text{BP}_n^{(j)}(s_n)} \text{Var}
\]

\[
\sum_{k=1}^{k_n-G_i^{(j)}} |\text{BP}_n^{(i,j,m)}(\bar{t}_n + t - s_n - R_i, \bar{t}_n + t + s - s_n - R_i)\rangle | \mathcal{F}_{s_n}
\]

by (6.11), again taking \( s_n \to \infty \) sufficiently slowly, and since \( e^{\alpha_n(t_n-\bar{t}_n)} = \sqrt{W_{s_n}^{(j)} W_{s_n}^{(j')}} \), so that the limit \( \tilde{W}_{s_n}^{(j)} \) has to be replaced by \( W_{s_n}^{(j)} \) \( W_{s_n}^{(j')} \), which is equal in distribution to \( W_{s_n}^{(j)} \).

**A conditional second moment method: variance.** We next bound, conditionally on \( F_{s_n} \), the variance of the sum on the right-hand side of (6.8). By conditional independence of \((\text{BP}_n^{(i,j,m)})_{i \geq 1}\),

\[
e^{-\alpha_n t_n} \text{Var}
\]

\[
\sum_{i \in \text{BP}_n^{(j)}(s_n)} \sum_{k=1}^{k_n-G_i^{(j)}} |\text{BP}_n^{(i,j,m)}(\bar{t}_n + t - s_n - R_i, \bar{t}_n + t + s - s_n - R_i)\rangle | \mathcal{F}_{s_n}
\]

\[
= e^{-\alpha_n t_n} \sum_{i \in \text{BP}_n^{(j)}(s_n)} \text{Var}
\]

\[
\sum_{k=1}^{k_n-G_i^{(j)}} |\text{BP}_n^{(i,j,m)}(\bar{t}_n + t - s_n - R_i, \bar{t}_n + t + s - s_n - R_i)\rangle | \mathcal{F}_{s_n}
\]

We bound

\[
\text{Var}
\]

\[
\sum_{k=1}^{k_n-G_i^{(j)}} |\text{BP}_n^{(i,j,m)}(\bar{t}_n + t - s_n - R_i, \bar{t}_n + t + s - s_n - R_i)\rangle | \mathcal{F}_{s_n}
\]

\[
\leq \mathbb{E}
\]

\[
\left( \sum_{k=1}^{k_n-G_i^{(j)}} |\text{BP}_n^{(i,j,m)}(\bar{t}_n + t - s_n - R_i)\rangle | \mathcal{F}_{s_n}\right)^2
\]

\[
\leq \mathbb{E} \left[ |\text{BP}_n^{(i,j,m)}(\bar{t}_n + t - s_n - R_i)\rangle | \mathcal{F}_{s_n}\right] = \mathbb{E} \left[ |\text{BP}_n^{(i,j,m)}(\bar{t}_n + t - s_n - R_i)\rangle | \mathcal{F}_{s_n}\right]^2 = \mathbb{E} \left[ R_i, \bar{t}_n\right].
\]

By the \( n \)-dependent version of Proposition 4.1(b) in Proposition 4.1(d), for each \( n \geq 1 \),

\[
\sup_{t \geq 0} \{ e^{-\alpha_n t} \mathbb{E} \left[ |\text{BP}_n^{(i,j,m)}(t)\rangle|^2 \right] \} \leq C K_n.
\]
As a result,
\[
e^{-2\alpha_nt_n}\Var\left( \sum_{i \in \text{BP}_n^{(j)}(s_n)} \sum_{k=1}^{k_n-O_n^{(j)}} |\text{BP}_{n,k}^{(i,j,m)}(\bar{t}_n + t - s_n - R_i, \bar{t}_n + t + s - s_n - R_i)\rangle | \mathcal{F}_{s_n} \right) \\
\leq e^{-2\alpha_nt_n} \sum_{i \in \text{BP}_n^{(j)}(s_n)} \mathbb{E}\left[ |\text{BP}_{n,k}^{(i,j,m)}(\bar{t}_n + t - s_n - R_i)|^2 | R_t, \bar{t}_n \right] \\
\leq CK_ne^{-2\alpha_nt_n} \sum_{i \in \text{BP}_n^{(j)}(s_n)} e^{2\alpha_n(t_n-t-s_n-R_i)} \\
= CK_ne^{2\alpha_n(\bar{t}_n-t_n)+2\alpha_n t} \sum_{i \in \text{BP}_n^{(j)}(s_n)} e^{-2\alpha_nR_i} = O_p(1)K_ne^{-2\alpha_n s_n} \sum_{i \in \text{BP}_n^{(j)}(s_n)} e^{-2\alpha_nR_i},
\]
since \(e^{2\alpha_n(\bar{t}_n-t_n)+2\alpha_n t} = O_p(1)\). We can bound this further as in (6.6) and (6.7) by
\[
K_ne^{-2\alpha_n s_n} \sum_{i \in \text{BP}_n^{(j)}(s_n)} e^{-2\alpha_nR_i} \leq K_ne^{-\alpha_n s_n} \left( e^{-\alpha_n s_n} |\text{BP}_n^{(j)}(s_n)\rangle \right) = O_p(1)K_ne^{-\alpha_n s_n},
\]
which is \(o_p(1)\) precisely when \(K_n e^{-\alpha_n s_n} = o(1)\). Since we are free to choose \(K_n\), we can choose it such that \(K_n e^{-\alpha_n s_n} = o(1)\) indeed holds. By (6.18) and (6.19), the sum on the right-hand side of (6.8) is, conditionally on \(\mathcal{F}_{s_n}\), concentrated around its asymptotic conditional mean given in (6.14). As a result, (6.1) follows. This completes the proof of Proposition 2.3(a).

\textbf{Proof of Proposition 2.3(b).} In order to prove Proposition 2.3(b), we compare the statement of Proposition 2.3(b) with that of Proposition 2.3(a). Let \(m = |\text{SWT}^{(j)}_{\leq k(t_n,y)}[\bar{t}_n + t, \bar{t}_n + t + s]|\), so that \(m \overset{p}{\to} \infty\) on the event that \(\mathcal{W}_{s_n}^{(1)} \mathcal{W}_{s_n}^{(2)} > 0\), and consider the sum \(\sum_{i=1}^{m} X_i^*\), where \(X_i^* = d_{V_i} - 1\) are forward degrees of free vertices after time \(\bar{t}_n + t\), i.e., from the vertices \([n]\), we remove the set \(S_m\) of all vertices of which at least one half-edge appeared in \((\text{SWT}(s))_{s \leq \bar{t}_n + t}\). We will prove that, conditionally on \(\mathcal{F}_{\bar{t}_n+t}\) with \(t < B_n\),
\[
\frac{1}{m\nu_n} \sum_{i=1}^{m} X_i^* \overset{p}{\to} 1,
\]
and then the proof of Proposition 2.3(b) follows from the proof of Proposition 2.3(a) and the fact that \(\nu_n \to \nu\).

Without loss of generality, we may assume that \(B_n\) in (5.22) holds, so that \(t < B_n\) implies that \(|S_m| \leq \bar{m}_n\), where \(\bar{m}_n = \sqrt{n} (\log n)^{1/4}\) as in (5.54). As a result the sequence \((d_i)_{i \in [n]}|S_m\) satisfies Condition 1.1 whenever \((d_i)_{i \in [n]}\) does. Hence, Lemma 5.3 holds with \(B_i\) replaced by \(X_i^*\) so that in particular, from the Markov inequality, conditionally on \(\mathcal{F}_{\bar{t}_n+t}\) and for every sequence \(K_n \to \infty\) satisfying \(K_n^2 = o(n/\bar{m}_n)\),
\[
\frac{1}{m} \sum_{i=1}^{m} X_i^* \mathbbm{1}_{\{X_i^* > K_n\}} \overset{p}{\to} 0.
\]
We use a conditional second moment method on \(\sum_{i=1}^{m} X_i^* \mathbbm{1}_{\{X_i^* \leq K_n\}}\), conditionally on \(\mathcal{F}_{\bar{t}_n+t}\). By (5.14) in Lemma 5.3,
\[
\mathbb{E}\left[ \sum_{i=1}^{m} X_i^* \mathbbm{1}_{\{X_i^* \leq K_n\}} \mid \mathcal{F}_{\bar{t}_n+t} \right] = m\nu_n(1 + o_p(1)).
\]
This gives the asymptotics of the first conditional moment of \(\sum_{i=1}^{m} X_i^* \mathbbm{1}_{\{X_i^* \leq K_n\}}\). For the second moment, we start by bounding the covariances. We note that, for \(1 \leq i < j \leq m\),
\[
\text{Cov}\left( X_i^* \mathbbm{1}_{\{X_i^* \leq K_n\}}, X_j^* \mathbbm{1}_{\{X_j^* \leq K_n\}} \mid \mathcal{F}_{\bar{t}_n+t} \right) \\
= \mathbb{E}\left[ X_i^* \mathbbm{1}_{\{X_i^* \leq K_n\}} \left( \mathbb{E}[X_j^* \mathbbm{1}_{\{X_j^* \leq K_n\}} \mid \mathcal{F}_{\bar{t}_n+t}, X_i^*, \ldots, X_j^*] - \mathbb{E}[X_j^* \mathbbm{1}_{\{X_j^* \leq K_n\}} \mid \mathcal{F}_{\bar{t}_n+t}] \right) \mid \mathcal{F}_{\bar{t}_n+t} \right] - \mathbb{E}\left[ X_i^* \mathbbm{1}_{\{X_i^* \leq K_n\}} \mid \mathcal{F}_{\bar{t}_n+t} \right].
\]
By (5.14) in Lemma 5.3, as well as the fact that $i \leq \overline{m}_n = o(n)$,
\[ 
\mathbb{E}[X_j^* \mathbb{1}_{\{X_j^* \leq K_n\}} | \mathcal{F}_{t_n+t}, X_1^*, \ldots, X_j^*] - \mathbb{E}[X_j^* \mathbb{1}_{\{X_j^* \leq K_n\}} | \mathcal{F}_{t_n+t}] = o_p(1), 
\] (6.24)
so that also
\[ 
\text{Cov}\left(X_j^* \mathbb{1}_{\{X_j^* \leq K_n\}}, X_j^* \mathbb{1}_{\{X_j^* \leq K_n\}} | \mathcal{F}_{t_n+t}\right) = o_p(1). 
\] (6.25)
Further, a trivial bound on the second moment together with (5.14) in Lemma 5.3 yields that
\[ 
\text{Var}\left(X_j^* \mathbb{1}_{\{X_j^* \leq K_n\}} | \mathcal{F}_{t_n+t}\right) \leq K_n \mathbb{E}[X_j^* | \mathcal{F}_{t_n+t}] = K_n \nu_n(1 + o_p(1)). 
\] (6.26)
As a result, whenever $K_n m = o(m^2)$, and $k_n^2 = o(n/\overline{m}_n)$,
\[ 
\text{Var}\left(\sum_{i=1}^{m} X_i^* \mathbb{1}_{\{X_i^* \leq K_n\}} | \mathcal{F}_{t_n+t}\right) = o_p(m^2), 
\] (6.27)
which together with (6.22) proves that, conditionally on $\mathcal{F}_{t_n+t}$,
\[ 
\frac{1}{m \nu_n} \sum_{i=1}^{m} X_i^* \mathbb{1}_{\{X_i^* \leq K_n\}} \xrightarrow{p} 1. 
\] (6.28)
Together with (6.21), this proves (6.20), as required.

7. The PPP limit for collision edges: Proof of Theorem 3.1

Recall that $(\mathcal{F}_t)_{t \geq 0}$ is the filtration generated by all the randomness used in the construction up to time $t$, i.e.,
\[ 
\mathcal{F}_t = \sigma\left((\text{SWT}(s), \text{BP}_n(s), \text{BP}(s))_{s \in [0,t]}\right). 
\]
We will investigate the number of collision edges $(x_i, P_{x_i})$ with $I(x_i) = j \in \{1, 2\}$, $H(x_i) \leq k_n(t_n, x), H(P_{x_i}) \leq k(t_n, y)$ and $R_{t_n}^{(\text{col})}(P_{x_i}) \in [0, s)$ created in the time interval $[t_n + t, t_n + t + \varepsilon)$, where $\varepsilon > 0$ is small. We let $\mathcal{I} = [a, b] \times [j] \times (-\infty, x] \times (-\infty, y] \times [0, s]$ be a subset of $\mathcal{S}$, and we prove that
\[ 
\mathbb{P}(\Pi_n(\mathcal{I}) = 0 | \mathcal{F}_{s_n}) \xrightarrow{p} \exp\left\{- \int_a^b \frac{2\nu \int_R(0)}{\text{E}[D]} e^{2\alpha t} \Phi(x) \Phi(y) F_R(s) dt\right\}. 
\] (7.1)
By [28, Theorem 4.7], this proves the claim.

We split
\[ 
\mathcal{I} = \bigcup_{l=1}^{N} \mathcal{I}^{(c)}_l, 
\] (7.2)
where $\mathcal{I}^{(c)}_l = [\ell^{(c)}_l, \ell^{(c)}_l + \varepsilon] \times [j] \times (-\infty, x] \times (-\infty, y] \times [0, s)$, with $\ell^{(c)}_l = a + \varepsilon$ and $\varepsilon = (b-a)/N$, with $N \in \mathbb{N}$. We will let $\varepsilon \downarrow 0$ later on. For a fixed $\varepsilon > 0$, we say that a collision edge $(x_i, P_{x_i})$ is a first round collision edge when there exists $l \in [N]$ and a half-edge $y \in \text{AH}(\ell^{(c)}_{l-1})$ such that $y$ is found by the liquid in the time interval $\mathcal{I}^{(c)}_l$, $y$ is paired to the half-edge $P_y$ whose sibling half-edge $x_i$ is paired to $P_{x_i} \in \text{AH}(\ell^{(c)}_{l-1})$ with $I(y) = j \neq I(P_{x_i}) = 3 - j$. We call all other collision edges second round collision edges. The second round collision edges are such that a half-edge $y$ is found by the liquid in the time interval $\mathcal{I}^{(c)}_l$ (the first round), $y$ is paired to the half-edge $P_y$, one of the sibling half-edges $x_i$ of $y$ is then also found by the liquid in the time interval $\mathcal{I}^{(c)}_l$ (the second round) and is paired to a half-edge $P_{x_i}$, whose sibling half-edge $z$ is paired to $P_z \in \text{AH}(\ell^{(c)}_{l-1})$ with $I(z) = j \neq I(P_z) = 3 - j$. When $\varepsilon > 0$ is quite small, the latter seems less likely, which is why we start with the first round collision edges.

Denote the point processes of first and second round collision edges by $\Pi_n^{(\text{FR})}$ and $\Pi_n^{(\text{SR})}$, so that $\Pi_n = \Pi_n^{(\text{FR})} + \Pi_n^{(\text{SR})}$. The next two lemmas investigate the point processes $\Pi_n^{(\text{FR})}$ and $\Pi_n^{(\text{SR})}$.
Lemma 7.1 (PPP limit for the first round collision edges). For every $s \geq 0$, $x, y \in \mathbb{R}$, $j \in \{1, 2\}$, $\varepsilon > 0$ and $\ell \in [N]$, as $n \to \infty$,

$$
\mathbb{P}(\Pi_{n}^{(FR)}(I_{\ell}^{(c)}) = 0 \mid \mathcal{F}_{t_{\ell-1}^{(c)}}) \xrightarrow{p} \exp\left\{-\frac{2\nu}{\mathbb{E}[D]}e^{2\alpha_{\ell-1}^{(c)}\Phi(x)\Phi(y)F_R(s)F_n(\varepsilon)}\right\}.
$$

(7.3)

Proof. The number of half-edges $z \in \text{AH}(\bar{t}_{n}^{\ell} + t_{\ell-1}^{(c)})$ that are found by the liquid having $I(z) = j$ and $H(z) \leq k_n(t, x)$ is equal to

$$
|\text{SWT}_{\leq k_n(t, x)}[\bar{t}_n^{\ell} + t_{\ell-1}^{(c)}, \bar{t}_n + t_{\ell-1}^{(c)} + \varepsilon]|.
$$

(7.4)

Fix such a half-edge $z$, and note that it is paired to $P_z$ that has $X_z^* = d_V P_z - 1$ sibling half-edges. For each of these half-edges we test whether it is paired to a half-edge in $\text{AH}(\bar{t}_n^{\ell} + t_{\ell-1}^{(c)})$ or not. Therefore, the total number of tests performed in the time interval $[t_{\ell-1}^{(c)}, t_{\ell}^{(c)}]$ is equal to

$$
\sum_{z} X_z^*1\{z \in \text{SWT}_{\leq k_n(t, x)}[\bar{t}_n^{\ell} + t_{\ell-1}^{(c)}, \bar{t}_n + t_{\ell-1}^{(c)}]\}.
$$

(7.5)

By construction, we test whether these half-edges are paired to half-edges that are incident to the SWT or not. Each of these edges is paired to a half-edge $w \in \text{AH}(\bar{t}_n^{\ell} + t_{\ell-1}^{(c)})$ with $I(w) = 3-j$ and thus creating a collision edge) and $H(w) \leq k(t, n)$ and $R_{\bar{t}^{\ell} + t_{\ell-1}^{(c)}}(w) \in [0, s)$ with probability equal to

$$
\frac{1}{t_n - o(n)}|\text{SWT}_{\leq k(t, n, y)}[\bar{t}_n^{\ell} + t_{\ell-1}^{(c)}, \bar{t}_n + t_{\ell-1}^{(c)} + s]|.
$$

(7.6)

Therefore, for $\varepsilon > 0$, conditionally on $\mathcal{F}_{t_{\ell-1}^{(c)}}$, the probability that none of the half-edges found in the time interval in between $[\bar{t}_n^{\ell} + t_{\ell-1}^{(c)}, \bar{t}_n + t_{\ell-1}^{(c)}]$ creates a collision edge is asymptotically equal to

$$
\prod_{w \in \text{SWT}_{\leq k(t, n, y)}[\bar{t}_n^{\ell} + t_{\ell-1}^{(c)}, \bar{t}_n + t_{\ell-1}^{(c)}]} \left(1 - \frac{1}{t_n - o(n)}|\text{SWT}_{\leq k(t, n, y)}[\bar{t}_n^{\ell} + t_{\ell-1}^{(c)}, \bar{t}_n + t_{\ell-1}^{(c)} + s]|\right)^{X_w^{*}}
$$

(7.7)

$$
\xrightarrow{p} \exp\left\{-\frac{\nu}{\mathbb{E}[D]}e^{2\alpha_{\ell-1}^{(c)}\Phi(x)\Phi(y)F_R(s)F_R(\varepsilon)}\right\},
$$

where we use (2.45), that $e^{2\alpha_{\ell-1}t_{\ell}} = n^{-1}$, and that $\ell_n = n\mathbb{E}[D_n]$ with $\mathbb{E}[D_n] \to \mathbb{E}[D]$. The factor 2 in (7.3) is caused by the two possibilities $j \in \{1, 2\}$.

Lemma 7.2 (A bound on the second round collision edges). For $x, y \in \mathbb{R}$, $j \in \{1, 2\}$, $\varepsilon > 0$ and $\ell \in [N]$, as $n \to \infty$,

$$
\mathbb{P}(\Pi_{n}^{(SR)}(I_{\ell}^{(c)}) \geq 1 \mid \mathcal{F}_{t_{\ell-1}^{(c)}}) = O_{s}(1)F_R(\varepsilon)F_\ell(\varepsilon).
$$

(7.8)

Proof. By analogous arguments as above, the expected number of second round collision edges is of order

$$
O_{s}(1)e^{2\alpha_{\ell}^{(c)}\Phi(x)\Phi(y)F_R(s)F_R(\varepsilon)F_\ell(\varepsilon)},
$$

(7.9)

since one of the half-edges $z$ that is found by the liquid in the time interval $[\bar{t}_n^{\ell} + t_{\ell-1}^{(c)}, \bar{t}_n + t_{\ell}^{(c)}]$ needs to satisfy that one of the $d_V P_z - 1$ half-edges has weight at most $\varepsilon$, and which, upon being found, needs to create a collision edge.

Now we are ready to complete the proof of Theorem 3.1. We use that

$$
\mathbb{P}(\Pi_{n}^{0}(I) = 0 \mid \mathcal{F}_{n}) = \mathbb{E}\left[\prod_{\ell=1}^{N} \mathbb{P}(\Pi_{n}(I_{\ell}^{(c)}) = 0 \mid \mathcal{F}_{t_{\ell-1}^{(c)}}) \mid \mathcal{F}_{n}\right].
$$

(7.10)

We start with the upper bound, for which we use that

$$
\mathbb{P}(\Pi_{n}(I_{\ell}^{(c)}) = 0 \mid \mathcal{F}_{t_{\ell-1}^{(c)}}) \leq \mathbb{P}(\Pi_{n}^{(FR)}(I_{\ell}^{(c)}) = 0 \mid \mathcal{F}_{t_{\ell-1}^{(c)}})
$$

(7.11)

$$
\xrightarrow{p} \exp\left\{-\frac{2\nu}{\mathbb{E}[D]}e^{2\alpha_{\ell-1}^{(c)}\Phi(x)\Phi(y)F_R(s)F_R(\varepsilon)}\right\},
$$
by Lemma 7.1. We conclude that
\begin{equation}
\mathbb{P}(\Pi_n(I) = 0 \mid \mathcal{F}_{s_n}) \leq \mathbb{E}\left[ \prod_{\ell=1}^{N} \exp \left\{ - \frac{2\nu}{\mathbb{E}[D]} e^{2\alpha t_{\ell-1}^{(c)}} \Phi(x)\Phi(y)F_R(s)F_R(\varepsilon) \right\} \mid \mathcal{F}_{s_n} \right] \tag{7.12}
\end{equation}

\begin{equation}
= \exp \left\{ - \sum_{\ell=1}^{N} \frac{2\nu}{\mathbb{E}[D]} e^{2\alpha t_{\ell-1}^{(c)}} \Phi(x)\Phi(y)F_R(s)F_R(\varepsilon) \right\}
\end{equation}

\begin{equation}
\rightarrow \exp \left\{ - \frac{2\nu}{\mathbb{E}[D]} f_R(0) \int_{a}^{b} e^{2\alpha t} \Phi(x)\Phi(y)F_R(s)dt \right\},
\end{equation}

since \( \lim_{\varepsilon \downarrow 0} F_R(\varepsilon)/\varepsilon = f_R(0) \), and the Riemann approximation

\begin{equation}
\varepsilon \sum_{\ell=1}^{N} e^{2\alpha t_{\ell-1}^{(c)}} \rightarrow \int_{a}^{b} e^{2\alpha t} dt.
\end{equation}

This proves the upper bound.

For the lower bound, we instead bound
\begin{equation}
\mathbb{P}(\Pi_n(I) = 0 \mid \mathcal{F}_{s_n}) \geq \mathbb{E}\left[ \prod_{\ell=1}^{N} \mathbb{P}(\Pi_n^{(PR)}(I_{\ell}^{(c)}) = 0 \mid \mathcal{F}_{t_{\ell-1}^{(c)}}) \mid \mathcal{F}_{s_n} \right] \tag{7.14}
\end{equation}

\begin{equation}
- \mathbb{E}\left[ \left( \sum_{\ell=1}^{N} \mathbb{P}(\Pi_n^{(SR)}(I_{\ell}^{(c)}) \geq 1 \mid \mathcal{F}_{t_{\ell-1}^{(c)}}) \right) \wedge 1 \mid \mathcal{F}_{s_n} \right].
\end{equation}

The first term has already been dealt with, the second term is, by Lemma 7.2, bounded by
\begin{equation}
\mathbb{E}\left[ \left( O_{p}(1) \sum_{\ell=1}^{N} F_R(\varepsilon)F_{\xi}(\varepsilon) \right) \wedge 1 \mid \mathcal{F}_{s_n} \right] = o_{p}(1), \tag{7.15}
\end{equation}

as \( \varepsilon \downarrow 0 \), by dominated convergence, since \( F_R(\varepsilon) = \varepsilon f_R(0)(1 + o(1)) \) and \( F_{\xi}(\varepsilon) = o(1) \).
