Satellite attitude control

ABSTRACT

An alternative stability analysis theorem for nonlinear periodic discrete-time systems is presented. The developed theorem offers a trade-off between conservativeness and complexity of the corresponding stability test. In addition, it yields a tractable stabilizing controller synthesis method for linear periodic discrete-time systems subject to polytopic state and input constraints. It is proven that in this setting, the proposed synthesis method is strictly less conservative than available tractable synthesis methods. The application of the derived method to the satellite attitude control problem results in a large region of attraction.

1. Introduction

This work deals with stability and stabilization of periodically time-varying systems, or shortly, periodic systems. Stability analysis and stabilization of periodic systems are typically handled by means of periodically time-varying standard Lyapunov functions (LFs), see Jiang and Wang (2002) for the nonlinear case and Bittanti and Colaneri (2009) for the linear case. For most of the available controller synthesis methods for periodic systems, existence of a periodically time-varying LF for the closed-loop dynamics can be derived, either directly or by the converse result in Jiang and Wang (2002). Consider methods based on the periodic Riccati equation Bittanti, Colaneri, and De Nicolao (1991) and Varga (2008), output feedback schemes De Souza and Trofino (2000), H2 synthesis for the case of linear periodic systems with polytopic uncertainties Farges, Peaucelle, Arzelier, and Daafouz (2007),

eigenvalue assignment Brunovsky (1970), Kabamba (1986) controllability Longhi and Zulli (1995), model predictive control Böhm (2011), Gondhalekar and Jones (2011), and control with saturation Zhou, Zheng, and Duan (2011). In the monograph (Bittanti & Colaneri, 2009, Chapter 13), a thorough exposition of existing results on stabilization techniques, including also frequency domain considerations or lifting techniques, is presented.

In the presence of constraints, however, stability analysis based on periodically time-varying standard LFs can yield a conservative region of attraction, as shown recently in Böhm, Lazar, and Allgöwer (2012). Therein, a relaxed stability analysis theorem was derived for autonomous nonlinear periodic systems. The main idea behind this relaxation is that the Lyapunov function is not required to decrease at each time instant, as in Bittanti and Colaneri (2009) or in Jiang and Wang (2002) for the linear case, but at each period. This paper considers stabilization of linear periodic systems with inputs, subject to polytopic state and input constraints, by means of linear periodic state-feedback control laws. The presence of input constraints further motivates the need for a relaxation of the classical stability analysis theorems Bittanti and Colaneri (2009) and Jiang and Wang (2002). For the case of periodic systems with inputs, however, the relaxed periodic Lyapunov conditions in Böhm et al. (2012) lead to a nonlinear and non-convex optimization problem which is not tractable.

Motivated by the current status, we propose an alternative stability analysis theorem for nonlinear periodic systems. This new result allows the establishment of a tractable constrained synthesis
method for linear periodic systems, by choosing quadratic periodic Lyapunov functions. We show how the constrained synthesis problem with linear periodic state-feedback can be solved by decomposing the original non-convex optimization problem in a finite set of semi-definite optimization problems having linear matrix inequalities (LMIs) as constraints. The equivalence between the original non-convex problem and the set of semi-definite optimization problems is formally proven. The method is applied successfully in the challenging magnetic satellite attitude control problem. The developed synthesis method yields a large region of attraction for the resulting closed-loop system while providing non-trivial performance guarantees.

The remaining part of this paper is structured as follows. Existing results on Lyapunov stability for periodic systems are briefly discussed in Section 2. The problem formulation as well as solutions from existing approaches are presented in Section 3. The main results are established in Section 4. Application of the established results to the satellite attitude control problem is presented in Section 5, while conclusions are drawn in Section 6.

Notation and basic definitions: Let \( \mathbb{R}, \mathbb{R}_+, \mathbb{Z}, \) and \( \mathbb{Z}_+ \) denote the field of real numbers, the set of non-negative reals, the set of integer numbers and the set of non-negative integers, respectively. For every \( c \in \mathbb{R} \) and \( \Pi \subseteq \mathbb{R} \) we define \( \Pi_c := \{ x \in \Pi \mid x \geq c \} \), and similarly \( \Pi_{\leq c} := \Pi \) and \( \Pi_c := \mathbb{Z} \cap \Pi \). For \( N \in \mathbb{Z}_+ \), \( \Pi^N := \Pi \times \cdots \times \Pi \). For a vector \( x \in \mathbb{R}^n \), \( [x] \) denotes the ith element of \( x \) and \( \|x\| \) denotes its 2-norm, i.e., \( \|x\| := \sqrt{\sum_{i=1}^{n} |[x]|^2} \). The transpose of a matrix \( X \in \mathbb{R}^{n \times m} \) is denoted by \( X^T \). For a symmetric matrix \( Z \in \mathbb{R}^{n \times n} \) let \( \lambda_{\min}(Z) \), \( \lambda_{\max}(Z) \) denote its smallest (largest) eigenvalue. Moreover, for a block symmetric matrix \( Z = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \), where \( a, b, c \) are matrices of appropriate dimensions, the symbol \( * \) is used to denote the symmetric part, i.e., \( \begin{bmatrix} a & * \\ * & d \end{bmatrix} \). For the definition of functions of class \( \mathcal{K}, \mathcal{K}_\infty \) and \( \mathcal{K}_\ell \), refer to Böhm et al. (2012).

2. Preliminaries

Let \( n, m \in \mathbb{Z}_+ \) be integers and let \( \mathbb{X} : \mathbb{Z}_+ \to \mathbb{R}^n \) and \( U : \mathbb{Z}_+ \to \mathbb{R}^m \) be maps that assign to each \( k \in \mathbb{Z}_+ \), a subset of \( \mathbb{R}^n \) and a subset of \( \mathbb{R}^m \) respectively, which contain the origin in their interior. We consider time-varying nonlinear systems of the form

\[
x(k+1) = f(k, x(k), u(k)), \quad k \in \mathbb{Z}_+,
\]

where \( f : \mathbb{Z}_+ \times \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n \) is an arbitrary nonlinear map such that \( f(k, 0, 0) = 0 \), for all \( k \in \mathbb{Z}_+ \). The vector \( x(k) \in \mathbb{X}(k) \) is the system state at time \( k \in \mathbb{Z}_+ \) and \( u(k) \in U(k) \) is the system input at time \( k \in \mathbb{Z}_+ \).

Definition 1. The system (1) is called periodic if there exists an \( N \in \mathbb{Z}_+ \) such that for all \( k \in \mathbb{Z}_+ \), it holds (i) \( \mathbb{X}(k) = \mathbb{X}(k+N) \); (ii) \( U(k) = U(k+N) \); (iii) \( f(k, x, u) = f(k+N, x, u) \) for all \( x \in \mathbb{X}(k) \), for all \( u \in U(k) \). Furthermore, the smallest such \( N \in \mathbb{Z}_+ \) is called the period of system (1).

We consider a periodically time-varying state feedback control law \( g : \mathbb{Z}_+ \times \mathbb{R}^n \to \mathbb{R}^m \) such that \( g(k, 0) = 0 \), for all \( k \in \mathbb{Z}_+ \), \( g(k, x) = g(k+N, x) \), for all \( k \in \mathbb{Z}_+ \), and \( g(k, x(k)) \in U(k) \), for all \( k \in \mathbb{Z}_+ \) and for all \( x \in \mathbb{X}(k) \). We assume, for simplicity, that the period of the control law is equal to the period of system (1). The corresponding closed-loop system is

\[
x(k+1) = f(k, x(k), g(k, x(k))), \quad k \in \mathbb{Z}_+.
\]

System (2) is periodic with period \( N \), since \( f(k+N, x, g(k+N, x)) = f(k, x, g(k, x)) \). In what follows, let \( \mathbb{X}_0 := \{ x \in \mathbb{X} \mid c_i x \leq 1, \forall i, k \in \mathbb{Z}_+ \times \mathbb{Z}_+ \} \).
where \( p(k) \in \mathbb{Z}_{\geq 1} \), for all \( k \in \mathbb{Z}_+ \), is the number of hyperplanes that define set \( \mathbb{X}(k) \), and \( c_i(k+N) = c_i(k) \), for all \( i, k \in \mathbb{Z}_{\{1,p(k)\}} \times \mathbb{Z}_+ \). Similarly, we consider polytopic input constraints

\[
U(k) := \{ u \in \mathbb{R}^m : d_i(k)u \leq 1, \forall (i,k) \in \mathbb{Z}_{\{1,q(k)\}} \times \mathbb{Z}_+ \},
\]

where \( q(k) \in \mathbb{Z}_{\geq 1} \), for all \( k \in \mathbb{Z}_+ \), and \( d_i(k+N) = d_i(k) \in \mathbb{R}^{1 \times n} \) for all \( i, k \in \mathbb{Z}_{\{1,q(k)\}} \times \mathbb{Z}_+ \).

We are now ready to state the problem of interest.

**Problem 1.** Given system \((5)\), state and input constraints \(\mathbb{X}(k)\) \((8)\) and \(U(k)\) \((9)\) respectively, determine a stabilizing linear periodic state-feedback control law \((6)\) and a corresponding PPI sequence of sets \(\{\mathbb{X}(k)\}_{k \in \mathbb{Z}_{[0,N-1]}}\) with respect to the closed-loop system \((7)\).

### 3.1. Solutions based on existing stability analysis theorems

To solve Problem 1, consider quadratic periodic Lyapunov function candidates

\[
V(k,x) = x^T P(k)x,
\]

where \( P(k) \in \mathbb{S}^n_{++}, \) with \( P(k+N) = P(k) \) for all \( k \in \mathbb{Z}_+ \). The candidate Lyapunov function \((10)\) is upper and lower bounded by \( \alpha_1, \alpha_2 \in \mathcal{K}_\infty \).

\[
\alpha_1(y) := \min_{i \in \mathbb{Z}_{\{0,N-1\}}} |\lambda_{\min} P(i)| y^2,
\]

\[
\alpha_2(y) := \max_{i \in \mathbb{Z}_{\{0,N-1\}}} |\lambda_{\max} P(i)| y^2,
\]

i.e.,

\[
\alpha_1(\|x\|) \leq V(k,x) \leq \alpha_2(\|x\|),
\]

for all \( x \in \mathbb{R}^n \). In this setting, one can apply Theorem 1, which results in the periodic Lyapunov lemma (PLL), as formally stated next.

**Lemma 1** \(\text{(Bittanti & Colaneri, 2009)}\). Consider system \((7)\). Let \( \rho(k) \in \mathbb{R}_{\{0,1\}}, k \in \mathbb{Z}_{[0,N-1]} \), and \( P(k) \in \mathbb{S}^n_{++}, k \in \mathbb{Z}_{[0,N]} \) be positive definite matrices, with \( P(N) := P(0), \) which define sets \( \mathbb{X}(k) = \{ x \in \mathbb{R}^n : x^T P(k)x \leq 1 \} \) such that \( \mathbb{X}(k) \subseteq \mathbb{X}(k), \) for all \( k \in \mathbb{Z}_{[0,N-1]} \). If the matrix inequalities

\[
(A(k) + B(k)K(k)) + (A(k) + B(k)K(k))^T \leq \rho(k)P(k) \leq 0,
\]

(14)

hold for all \( k \in \mathbb{Z}_{[0,N-1]} \), then system \((7)\) is ES(\(\mathbb{E}(0)\)).

Next, it is shown how Theorem 2 could be applied to solve Problem 1. To this end, for all \( k \in \mathbb{Z}_{[0,N-1]} \) define the monodromy matrices Bittanti and Colaneri (2009)

\[
\Phi(k) := \prod_{i=0}^{N-1} (A(k+i) + B(k+i)K(k+i)).
\]

**Lemma 2.** Consider system \((7)\). Let \( \eta \in \mathbb{R}_{\{0,1\}}, P(k) \in \mathbb{S}^n_{++}, k \in \mathbb{Z}_{[0,N]} \) be positive definite matrices, with \( P(N) := P(0), \) which define sets \( \mathbb{X}(k) = \{ x \in \mathbb{R}^n : x^T P(k)x \leq 1 \} \) such that \( \mathbb{X}(k) \subseteq \mathbb{X}(k), \) for all \( k \in \mathbb{Z}_{[0,N-1]} \). If the matrix inequalities

\[
\Phi(k) + P(k) - \eta P(k) \leq 0,
\]

(15a)

\[
(A(k) + B(k)K(k)) + (A(k) + B(k)K(k))^T \leq \rho(k)P(k) \leq 0,
\]

(15b)

hold for all \( k \in \mathbb{Z}_{[0,N-1]} \), then system \((7)\) is AS(\(\mathbb{E}(0)\)).

**Remark 1.** The closed-loop system \((7)\) is a time-varying linear system with a finite number of time-invariant subsystems. Also, the corresponding periodic Lyapunov function \((10)\) is periodically time-varying. Since the upper and lower \( \mathcal{K}_\infty \) bounds \((11), (12)\) of the Lyapunov function \((10)\) are time-invariant, exponential stability of the closed-loop system \((7)\) can be deduced following the proof of Böhm et al. (2012, Theorem 9), by exploiting the specific form of \((11)\) and \((12)\). Consequently, if conditions \((15a), (15b)\) of Lemma 2 hold, then the system \((7)\) is ES(\(\mathbb{E}(0)\)). The formal details of this straightforward derivation are omitted for brevity.

**Remark 2.** Lemma 2 is a strict relaxation of the result stated in Lemma 1. Indeed, a feasible set of matrices \( P(k), k \in \mathbb{N}_{[0,N-1]} \), and periodic state feedback gains \( K(k), k \in \mathbb{N}_{[0,N-1]} \), that satisfies \((14)\), satisfies relations \((15)\) as well, but the converse is not true. Regarding computational aspects, the conditions \((14)\) of Lemma 1 can be reformulated as an equivalent semidefinite program, while finding a solution to the conditions \((15)\) of Lemma 2 requires solving a non-convex and nonlinear program. Therefore, it is of interest to establish a trade-off between the additional degree of freedom introduced by Lemma 2 and the tractability of the conditions of Lemma 1.

### 4. Main results

The first main result of this paper is an alternative stability analysis theorem for periodic nonlinear systems, which provides a trade-off between Theorems 1 and 2, as formally stated next.

**Theorem 3.** Let \( \{\mathbb{X}(k)\}_{k \in \mathbb{Z}_{[0,N-1]}} \) be a PPI sequence of sets w.r.t. \((2)\). Let \( \alpha_1, \alpha_2 \in \mathcal{K}_\infty \), scalars \( \rho(j) \in \mathbb{R}_{\{0,1\}}, \) \( j \in \mathbb{N}_{[0,N-1]} \), and \( x(\cdot) \) be a solution to \((2)\) with \( x(0) := \xi \in \mathbb{X}(0) \). Let \( V : \mathbb{R} \times \mathbb{X} \rightarrow \mathbb{R}_+ \) be a function, such that \( V(k,x) = V(k+N,x), \) for all \( k \in \mathbb{Z}_+ \), and moreover, for all \( j \in \mathbb{N}_{[0,N-1]} \), it holds that

\[
V(j + 1, x(j + 1)) \leq \rho(j)V(j, x(j)), \quad \forall x \in \mathbb{X}(0)
\]

\[
\alpha_1(\|x(j)\|) \leq V(k,x) \leq \alpha_2(\|x(j)\|), \quad \forall x \in \mathbb{X}(k)
\]

\[
0 \leq \rho(i) < 1.
\]

Then, system \((2)\) is AS(\(\mathbb{X}(0)\)).

**Proof.** From \((16a)\) and \((16b)\), for any \( j \in \mathbb{Z}_{[1,N]} \), it holds that

\[
\alpha_1(\|x(j)\|) \leq V(j,x(j)) \leq \rho(j + 1)V(j, x(j - 1)) \leq \rho(j - 1)\alpha_2(\|x(j - 1)\|),
\]

or

\[
\|x(j)\| \leq \alpha_1^{-1}(\rho(j - 1)\alpha_2(\|x(j - 1)\|)).
\]

Thus, relation \((4a)\) of Theorem 2 is satisfied with

\[
\tilde{a}_j(\cdot) := \alpha_1^{-1}(\rho(j - 1)\alpha_2(\|x(j - 1)\|)), \quad \forall j \in \mathbb{Z}_{[1,N-1]}.
\]

Moreover, from \((16a)\), for any \( k \in \mathbb{Z}_+ \) and for any \( x(k) \in \mathbb{X}(k) \), it holds that

\[
V(k+N,x(j+N)) \leq \rho(N-1)V(j+N-1,x(j+N-1)).
\]

Applying the previous inequality successively, it holds that

\[
V(k+N,x(j+N)) \leq \rho(N-1)\rho(N-2)V(k+N-2,x(k+N-2)) \leq \cdots \leq \prod_{i=0}^{N-1} \rho(i)V(k,x(k))
\]

Taking into account \((16c)\), relation \((4c)\) of Theorem 2 is satisfied with \( \eta := \prod_{i=0}^{N-1} \rho(i) \in \mathbb{R}_{\{0,1\}} \). Thus, by Theorem 2, system \((2)\) is AS(\(\mathbb{X}(0)\)).
Remark 3. To compare the available stability analysis theorems observe the following: (i) Theorem 1 requires \( V(\cdot) \) to decrease at every time instant \( k \in \mathbb{Z}_+ \); (ii) Theorem 3 requires \( V(\cdot) \) not to increase at every time instant \( k \in \mathbb{Z}_+ \), and to decrease at every \( N \) time instants, i.e., at every period; (iii) Theorem 2 requires \( V(\cdot) \) to decrease at every period. Furthermore, notice that condition (16c) does not fix a particular time instant when the decrease should take place, within each period.

Remark 4. While existence of a function \( V(\cdot) \) that satisfies conditions of Theorems 1–3 is necessary and sufficient\(^2\) for the system (2) to be \( \text{AS}(\mathcal{X}_0) \), the feasible solution sets of the underlying conditions are ordered as follows: A function \( V(\cdot) \) satisfying conditions (3) of Theorem 1 satisfies conditions (16) of Theorem 3, which in turn satisfies conditions (15) of Theorem 2. The opposite is not true. Since Theorem 3 still provides a strict relaxation of Theorem 1, it is of further interest to utilize Theorem 3 for solving Problem 1. To this end, consider the following result.

**Theorem 4.** Consider system (5) and constraints \( \mathcal{X}(k) \{ 8 \}, \mathcal{U}(k) \{ 9 \} \). Let \( \rho(\cdot) \in \mathbb{R}_{[0,1]} \times \mathcal{X}(k) \in \mathcal{S}^{n	imes n} \), \( \mathcal{Y}(k) \in \mathbb{R}^{m \times n} \), for all \( k \in \mathbb{Z}_{[0, N-1]} \), where \( X(N) := X(0), Y(N) := Y(0), \) be a feasible solution to the following set of matrix inequalities, for all \( k \in \mathbb{Z}_{[0, N-1]} \), for all \( i \in \mathbb{Z}_{[1, p(k)]} \) and all \( j \in \mathbb{Z}_{[1, q(k)]} \):

\[
\begin{pmatrix}
\rho(k)X(k) & \ast \\
A(k)X(k) + B(k)Y(k) & X(k+1)
\end{pmatrix} \succeq 0,
\]

\[
0 \leq \sum_{l=0}^{N-1} \rho(l) < N,
\]

\[
\begin{pmatrix} 1 & \ast \\ X(k)c(k)^\top & X(k) \end{pmatrix} \succeq 0,
\]

\[
\begin{pmatrix} 1 & \ast \\ Y(k)d(k)^\top & X(k) \end{pmatrix} \succeq 0.
\]

Then, the sequence \( \{\mathcal{E}(k)\}_{k \in \mathbb{Z}_{[0, N-1]}} \), where \( \mathcal{E}(k) := \{x \in \mathbb{R}^n : x^TX(k)^{-1}x \leq 1\} \), \( k \in \mathbb{Z}_{[0, N-1]} \), is PPI for the closed-loop system (7) with periodic linear state feedback control law \( u(k, x) = Y(k)X(k)^{-1}x \), \( u(k + 1, x) = u(k, x) \) for all \( k \in \mathbb{Z}_+ \). Moreover, system (7) is \( \text{ES}(E(0)) \).  

**Proof.** First, we show that the sets \( \mathcal{E}(k), k \in \mathbb{Z}_{[0, N-1]} \), are contained in \( \mathcal{X}(k) \) and \( \mathcal{U}(k) \) for all \( k \in \mathbb{Z}_{[0, N-1]} \), where

\[
\mathcal{U}_k := \{x \in \mathbb{R}^n : d_k(k)Y(k)X(k)^{-1}x \leq 1, \forall i, k \in \mathbb{Z}_{[1, p(k)]} \times \mathbb{Z}_+ \},
\]

for all \( k \in \mathbb{Z}_{[0, N-1]} \). Applying the Schur complement in (17c) and exploiting the periodicity of \( \mathcal{E}(k) \) we obtain

\[
c_kc_k^\top X_k \leq 1, \forall i, k \in \mathbb{Z}_{[1, p(k)]} \times \mathbb{Z}_+.
\]

From Athanasopoulos, Lazar, Böhü, and Allgöwer (2013, Lemma 12), inequality (18) implies \( \mathcal{E}(k) \subset \mathcal{X}(k) \), for all \( k \in \mathbb{Z}_+ \). Equivalently, applying the Schur complement in (17d) we obtain

\[
d_kY(k)X(k)^{-1}Y(k)\tilde{d}_k(k)^\top \leq 1,
\]

for all \( j, k \in \mathbb{Z}_{[1, q(k)]} \times \mathbb{Z}_+ \). From Athanasopoulos et al. (2013, Lemma 12), inequality (19) implies \( \mathcal{E}(k) \subset \mathcal{U}_k \), for all \( k \in \mathbb{Z}_+ \).
Lemma 3. Consider system (5), constraints $\mathcal{X}(k)$ (8) and $\mathcal{Y}(k)$ (9), Then, the matrix inequalities (17) define a nonempty feasible solution set if and only if there exists an index $k^* \in \mathbb{Z}_{0,N-1}$ such that Problem 2 is feasible with $k = k^*$.

Proof. Suppose Problem 2 is feasible for a $k = k^* \in \mathbb{Z}_{0,N-1}$. Then, relations (17) are also feasible setting $\rho(k) = 1$, for all $k \in \mathbb{Z}_{0,N-1} \setminus \{k^*\}$, $\rho(k) := \overline{\rho}$, and $X(k^*)$, $Y(k^*)$, $X(k)$, $Y(k)$, $k \in \mathbb{Z}_{0,N-1}$, the solutions to Problem 2. Conversely, suppose that conditions (17) have a nonempty feasible solution set. Then, there exists at least one $k \in \mathbb{Z}_{0,N-1}$ such that $\rho(k^*) < 1$. Setting $k := k^*$ and $\overline{\rho} := \rho(k^*)$ the corresponding matrix inequalities (25b)–(25e) in Problem 2 are satisfied. Moreover, for any $k \in \mathbb{Z}_{0,N-1} \setminus \{k^*\}$ such that $\rho(k) < 1$, relation (17a) implies

\[
\begin{bmatrix}
X(k) & A(k)X(k) + B(k)Y(k) & X(k+1)
\end{bmatrix} \geq (1 - \rho(k)) X(k) \geq 0.
\]

Thus, (25a) is also satisfied, and consequently, Problem 2 has a solution for $k = k^*$.

Remark 5. Comparison of conditions (17a) of Theorem 4 with condition (25b) in Problem 2, reveals the significance of the previous result. Lemma 3 shows that existence of a feasible solution to the constraint set (17), which involves $N$ BSIs, is equivalent to existence of a solution in (at least) one of the $N$ feasibility problems (24)–(25), which involve a single bilinear term, i.e., the product of the scalar $\overline{\rho}$ and the matrix $X(k)$ in (25b).

Furthermore, since the single bilinear term in (25b) consists of a matrix and the constrained nonnegative scalar $\overline{\rho} \in \mathbb{R}_{+}$, solution of Problem 2 is equivalent to solving a series of LMIIs via bisection, which is guaranteed to converge to a feasible solution, if a feasible solution exists. Still, it is worth noting that the computational burden induced by the proposed method is higher than the one stemming from the application of the PPL synthesis method, which involves fewer decision variables and strict LMIIs, see e.g. Zhou et al. (2011). This is the price to be paid for exploiting the less conservative results of Theorem 4.

4.1. Additional synthesis objectives

In constrained synthesis, together with computing a stabilizing control law, it is of relevance to aim for a large basin of attraction $\mathcal{E}(0) \subseteq \mathcal{X}(0)$, where $\mathcal{E}(0) = \{x \in \mathbb{R}^n : x^\top X(0)x \leq 1\}$. To this end, a semi-definite optimization problem that is solved for every $k \in \mathbb{Z}_{0,N-1}$, maximizes the volume of $\mathcal{E}(0)$ and solves Problem 1, i.e.,

\[
\min_{\vec{X},\vec{Y},\overline{\mathcal{Y}},\pi(k),Y(k),k \in \mathbb{Z}_{0,N-1}} \text{trace}(\overline{\mathcal{Y}}),
\]

\[
\text{subject to (25).}
\]

Alternative optimization criteria that describe the size of $\mathcal{E}(0)$ can be chosen as well (see e.g. Boyd, El Ghaoui, Feron, & Balakrishnan, 1994).

Moreover, the quantities $\min_{0 \leq \rho(0)} \rho(0)$, where $\rho(0)$, $k \in \mathbb{Z}_{0,N-1}$, obtained from Theorem 4, and $\overline{\rho}$, obtained from Problem 2, represent the exponential decrease of the corresponding periodic Lyapunov functions at each period, and consequently the speed of convergence of the closed-loop system trajectories. Thus, the proposed method offers the possibility to embed performance specifications in the synthesis procedure. In order to achieve a desired decrease $\rho \in \mathbb{R}_{+}$ at each period for the closed-loop system, it is sufficient to replace (25d) by $0 \leq \rho(l) \leq N \overline{\rho}$.

An additional relevant problem is computation of a PPI sequence of sets $\{\mathcal{E}(k)\}_{k \in \mathbb{Z}_{0,N-1}}$ that includes a given set of initial conditions $\mathcal{X}_0 \subseteq \mathcal{X}(0)$. To this end, Problem 2 can be modified such that the first element $\mathcal{E}(0)$ of the PPI sequence includes $\mathcal{X}_0$.

First, consider a polytopic set $\mathcal{X}$ which is described as the convex hull of a finite set of vertices $v_i \in \mathbb{R}^n$, $i \in \mathbb{Z}_{1,q}$, i.e., $\mathcal{X} := \text{convhull}\{v_i, i \in \mathbb{Z}_{1,q}\}$.

Lemma 4. Let $E \in \mathbb{R}_{+}^{n,q}$, and $v_i \in \mathbb{R}^n$, for all $i \in \mathbb{Z}_{1,q}$, with $q \in \mathbb{Z}_2$. The polytope $\mathcal{X} := \text{convhull}\{v_i, i \in \mathbb{Z}_{1,q}\}$ is contained in the ellipsoid $E := \{x \in \mathbb{R}^n : x^\top Ex \leq 1\}$ if and only if $v_i^\top Ev_i \leq 1$, $\forall i \in \mathbb{Z}_{1,q}$.

Then, a stabilizing linear periodic state-feedback control law (6) and a PPI sequence of sets $\{\mathcal{E}(k)\}_{k \in \mathbb{Z}_{0,N-1}}$, such that $\mathcal{X}_0 \subseteq \mathcal{X}(0)$ can be computed from the solution of Problem 2 having the additional constraint

\[
\begin{bmatrix}
1 & X(0)
\end{bmatrix} \geq 0, \quad \forall i \in \mathbb{Z}_{0,q}.
\]

5. Satellite attitude control

A detailed comparison of the established results with the synthesis method that corresponds to the PLL Bittanti and Colaneri (2009) was provided in Athanasopoulos et al. (2013) for an illustrative, two-dimensional academic example. In order to also illustrate the applicability of the results to challenging real-life control problems, we consider the problem (see for example, Böhm, 2011; Lovera & Astolfi, 2004 and references therein) of attitude control of a low Earth orbit satellite via magnetic actuators.

The linearized continuous-time attitude dynamics of the satellite can be described Böhm (2011) by the following time-varying differential equation

\[
\dot{x}(t) = A_x x(t) + B_x u(t),
\]

where $A_x \in \mathbb{R}^{6 \times 6}$, $[A_{13}] = (1 - s_1) \omega_0$, $[A_{14}] = -4s_1 \omega_0^2$, $[A_{15}] = -3s_1 \omega_0 s_2$, $[A_{13}] = - (1 + s_1) \omega_0$, $[A_{16}] = s_1 \omega_0^2$, $[A_{14}] = \{A_{15}\} = \{A_{16}\} = 1$ and $[A_{11}] = 0$ for all the other index pairs $(i,j)$. Furthermore, $B_x(t) \in \mathbb{R}_+^{3 \times 6}$, $[B_x(t)]_{12} = -b_t(t) / J_2$, $[B_x(t)]_{11} = b_t(t)/J_2$, $[B_x(t)]_{13} = b_t(t)/J_3$, $[B_x(t)]_{12} = -b_t(t)/J_3$, $[B_x(t)]_{11} = -b_t(t)/J_1$, $[B_x(t)]_{13} = b_t(t)/J_1$ and $[B_x(t)]_{12} = 0$ for all the other index pairs $(i,j)$.

In detail, $s_1 := \frac{J_2 s_1}{J_3 s_2}$, $s_2 := \frac{J_1 s_2}{J_3 s_1}$, $s_3 := \frac{J_1 s_3}{J_2 s_1}$, where the constants $J_i$, $i \in \mathbb{Z}_{1,3}$ are the moments of inertia, with values $J_1 = 1250$ kg m$^2$, $J_2 = 2800$ kg m$^2$, $J_3 = 2600$ kg m$^2$. The input matrix $B_x(t)$ depends on the components $b_t(t)$, $i \in \mathbb{Z}_{1,3}$, of the Earth’s magnetic field, which are approximated by the trigonometric functions

\[
b_t(t) = a_t \cos(\omega_0 t + \beta_t \sin(\omega_0 t + \gamma_t) , i \in \mathbb{Z}_{1,3}.
\]

The satellite follows a circular orbit with an attitude of 600 km and an inclination angle of 77°. A full rotation around the Earth requires $T_0 = 96.7$ min, resulting in the frequency of $\omega_0 = 0.0649 \text{ rad/s}$. The relevant coefficients that describe sufficiently the components of the Earth’s magnetic field are $a_t = 2.2365 \times 10^{-6}$, $\omega_0 = -8.2537 \times 10^{-8}$, $\omega = 7.7377 \times 10^{-6}$, $\beta_t = 3.9411 \times 10^{-6}$, $\beta_t = 4.8422 \times 10^{-7}$, $\beta_t = 3.8422 \times 10^{-7}$, $\beta_t = 4.8420 \times 10^{-6}$, $\gamma_t = -2.8863 \times 10^{-6}$, $\gamma_t = 4.5491 \times 10^{-7}$, $\gamma_t = -1.4166 \times 10^{-7}$. Thus, the input matrix $B_x(t)$ is periodic with period $T_0$ such that $B_x(t + T_0) = B_x(t)$, for all $t \in \mathbb{R}_+$. The state vector $x \in \mathbb{R}^6$ consists of the three angular rates $\omega_0$, $i \in \mathbb{Z}_{1,3}$ and the three angles of the pointing error $\phi_i$, $i \in \mathbb{Z}_{1,3}$ with respect to
The continuous-time system (28) is discretized in all three angles of the resulting PPI sequences, for \( \phi_0 = 0 \), \( i \in \mathbb{Z}_{[1,3]} \). The set \( \mathcal{E}_0(0) \) is depicted in yellow color, while sets \( \mathcal{E}_s(s), s \in \mathbb{Z}_{[0,9]} \setminus \{0\} \) are depicted in gray. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

Remark 6. For the considered problem setting, a comparison with relevant methods was made. To this end, application of the PLL synthesis method (Lemma 1) did not result in a feasible solution, due to the preassigned initial condition set specification. On the other hand, application of the synthesis method that stems from the modification of the stability analysis method (Lemma 2) in Böhm et al. (2012), did not return a solution. In contrast, the computed region of attraction by the developed method spans a range of \([-60, 60]\) in all three angles of the pointing error, which is a significant range, while using only 10
feedback gain matrices. Last, comparing with predictive control approaches, the explicit model predictive control solution of Böhm (2011, Section 5.4), which employs 30 feedback gain matrices, reports a feasible solution for the initial condition \( x_0 = [0 0 0 30° 30° 30°]^T \).

6. Conclusions

An alternative stability analysis theorem for nonlinear periodic discrete-time systems was presented. In addition, the derived theorem was used to devise a tractable stabilizing controller synthesis method for linear periodic discrete-time systems subject to polytopic state and input constraints. The application of the derived method to satellite attitude control resulted in a large region of attraction.

Nikolaos Athanasopoulos (born in Patras, Greece, 1981) received the Diploma and Ph.D. degrees in Electrical and Computer Engineering from the University of Patras, Greece, in 2004 and 2010, respectively. In 2012, he was the recipient of an IEF Marie Curie Fellowship, hosted at the Eindhoven University of Technology. He is currently a Post-Doctoral Research Associate at the Control Systems group of the Electrical Engineering Department, at the Eindhoven University of Technology. His research interests include set theory methods for stability analysis and controller synthesis, control of constrained systems and polyhedral sets.

Mircea Lazar (born in Iasi, Romania, 1978) received his M.Sc. and Ph.D. in Control Engineering from the Technical University “Gh. Asachi” of Iasi, Romania (2002) and the Eindhoven University of Technology, The Netherlands (2006), respectively. For his Ph.D. thesis he received the EECI (European Embedded Control Institute) Ph.D. award. Since 2006 he has been an Assistant Professor in the Control Systems Group of the Electrical Engineering Faculty at the Eindhoven University of Technology. His research interests lie in stability theory, scalable Lyapunov methods and formal methods, and model predictive control.

Christoph Böhm (born in Kirchheim/Teck, Germany, 1980) graduated from the University of Stuttgart with a Diploma in Engineering Cybernetics in 2006. He was a Research Assistant at the Institute for Systems Theory and Automatic Control at the University of Stuttgart where he received his Ph.D. degree in 2011. From 2011 to 2013 he worked as a Mechatronics Research Engineer and Project Manager for the Hilti Aktiengesellschaft in Schaan, Principality of Liechtenstein. Since 2013, he is Senior Project Manager Mechatronics at the VAT Vakuumventile AG in Haag, Switzerland. His main research interests include control and estimation of mechatronic systems, nonlinear model predictive control, periodic systems, and applications to satellite control.

Frank Allgöwer is the Director of the Institute for Systems Theory and Automatic Control at the University of Stuttgart in Germany. He studied Engineering Cybernetics and Applied Mathematics in Stuttgart and at UCLA respectively and received his Ph.D. degree in Chemical Engineering from the University of Stuttgart. His main areas of interest are in cooperative control, predictive control and nonlinear control with application to a wide range of fields including systems biology. Since 2012 he serves as Vice President of the German Research Foundation DFG and as Vice President of the IEEE Control Systems Society. Starting in 2014, he is President Elect of the International Federation of Automatic Control (IFAC).
