Abstract

In this paper we consider the linear-quadratic differential game with an infinite planning horizon. We derive both necessary and sufficient conditions for existence of open-loop Nash equilibria for this game. Furthermore we show how all equilibria can be easily obtained from the eigenspace structure of a Hamiltonian matrix that is associated with the game.

Keywords: Linear quadratic differential games, open-loop Nash equilibria, solvability conditions, Riccati equations
1 Introduction

The last decade there has been an increasing interest to study several problems in economics using a dynamic game theoretical setting. In particular in the area of environmental economics and macro-economic policy coordination this is a very natural framework to model problems (see e.g. de Zeeuw et al. (1991), Mäler (1992), Kaitala et al. (1992) and Dockner et al. (1985), Tabellini (1986), Fershtman et al. (1987), Petit (1989), Levine et al. (1994), van Aarle et al. (1995), Douven et al (1995)). In e.g., policy coordination problems usually two basic questions arise i.e., first, are policies coordinated and, second, which information do the participating parties have. Usually both these points are rather unclear and, therefore, strategies for different possible scenarios are calculated and compared with each other. One of these scenarios is the so-called open-loop strategy. This scenario can be interpreted as that the parties simultaneously determine their strategy, next submit their strategies to some authority who then enforces these plans as binding commitments. So, this strategy is based on the assumption that the parties act non-cooperatively and that the only information they have on the model is its present state and the model structure. Obviously, since according this scenario the participating parties can not react to each other's policies, its economic relevance is mostly rather limited. However, as a benchmark to see how much parties can gain by playing other strategies, it plays a fundamental role. Due to its analytic tractability the open-loop Nash equilibrium strategy is in particular very popular for problems where the underlying model can be described by a (set of) linear differential equation(s) and the individual objectives the parties are striving for can be approximated by functions which quadratically penalize deviations from some (equilibrium) targets. Under the assumption that the parties only have a finite-planning horizon, this problem was first modeled and solved in a mathematically rigorous way by Starr and Ho in (1969) (see also Lukes et al (1971), Eisele (1982) and Engwerda (1996) for extensions and more precise formulations).

In Abou-Kandil et al. (1993), Weeren (1995) and Engwerda (1996) also convergence of this equilibrium strategy was studied if the planning horizon expands. Like in the optimal linear quadratic regulator theory it turns out that under some conditions it can be shown that this strategy converges. Furthermore, this converged solution is rather easy to calculate and much easier to implement than the finite planning horizon equilibrium solution.

So, the question arises whether this (converged) solution also solves the game if the parties consider an infinite-planning horizon. In Engwerda (1996) this problem was partly solved. That is, on the one hand a sufficient condition was given under which open-loop Nash equilibria exist and, on the other hand, for stable systems both a necessary and sufficient existence condition was derived. In this paper we will extend this approach. We will show that the condition derived in the above mentioned paper is also necessary and sufficient for the general case. We will conclude this paper by a discussion on the consequences of this result for numerical calculation of equilibrium solutions and by considering some special cases when (generically) a unique equilibrium exists.

The outline of the paper is as follows. In section two we start by stating the problem
analysed in this paper and present some preliminary properties. Section three contains the basic result, whereas section four contains the concluding remarks.

2 Preliminaries

In this paper we consider the problem where two parties (henceforth called players) try to minimize their individual quadratic performance criterion. Each player controls a different set of inputs to a single system, described by a differential equation of arbitrary order. As already mentioned in the introduction we assume that both players have to formulate their strategy already at the moment the system starts to evolve and this strategy can not be changed once the system runs. So, the players have to minimize their performance criterion based on the information that they only know the differential equation and its initial state. We are looking now for combinations of pairs of strategies of both players which are secure against any attempt by one player to unilaterally alter his strategy. That is, for those pairs of strategies which are such that if one player deviates from his strategy he will only lose. In the literature on dynamic games this problem is well-known as the open-loop Nash non-zero-sum linear quadratic differential game (see e.g. Starr and Ho (1969), Simaan and Cruz (1973), Başar and Olsder (1982) or Abou-Kandil and Bertrand (1986)). Formally the system we consider is as follows:

\[
\dot{x} = Ax + B_1u_1 + B_2u_2, \quad x(0) = x_0,
\]

where \(x\) is the \(n\)-dimensional state of the system, \(u_i\) is an \(m_i\)-dimensional (control) vector player \(i\) can manipulate, \(x_0\) is the initial state of the system, \(A, B_1,\) and \(B_2\) are constant matrices of appropriate dimensions, and \(\dot{x}\) denotes the time derivative of \(x\).

The performance criterium player \(i = 1, 2\) aims to minimize is:

\[\lim_{t_f \to \infty} J_i(u_1, u_2),\]

where

\[J_1(u_1, u_2) := \frac{1}{2} \int_0^{t_f} (x(t)^T Q_1 x(t) + u_1(t)^T R_{11} u_1(t)) \, dt,\]

and

\[J_2(u_1, u_2) := \frac{1}{2} \int_0^{t_f} (x(t)^T Q_2 x(t) + u_2(t)^T R_{22} u_2(t)) \, dt,\]

in which matrix \(R_{ii}\) is positive definite, \(Q_i\) is semi-positive definite and additionally is positive definite w.r.t. the controllability subspace \(< A, B_i >, \ i = 1, 2.\)

Note that usually in literature each player's performance criterium also includes a cross term, penalizing the control efforts of the other player. Since, however, this cross term does not play a role in the analysis of open-loop Nash equilibria, we dropped this term here (see any of the references quoted above).

The set of admissible control functions we consider, is given by \(U :=\)

\[\{ \begin{pmatrix} u_1(t) \\ u_2(t) \end{pmatrix}, t \in [0, \infty) \mid \lim_{t_f \to \infty} J_i(u_1, u_2) < \infty, \ i = 1, 2.\} \]
Note that $U$ depends on the initial state of the system. For simplicity of notation we omit, however, this dependency. Furthermore, it is clear that $u_i(.) \in L^2$, the set of square integrable functions, but that $U$ is not a linear subspace of $L^2$. First, since the zero-function will in general not belong to $U$ and, second, in general with $v, w \in U$, $v + w \notin U$. However, $U$ does satisfy the following important property:

Lemma 1:
Assume that both $v$ and $v + w$ are an element of $U$. Then for any real $\epsilon$ also $v + \epsilon w \in U$.

Proof:
First we introduce some notation.
Let $x_u$ denote the state trajectory obtained by using the control function $u$, that is,

$$x_u(t) := e^{At}x_0 + \int_0^t e^{A(t-\tau)}(B_1 B_2)u(\tau)d\tau.$$ 

Since by assumption both $v$ and $v + w$ belong to $U$, $x_v(t)$ and $x_{v+w}(t)$ converge to zero if $t \to \infty$. So, $x_v(t) - x_{v+w}(t) = \int_0^t e^{A(t-\tau)}(B_1 B_2)w(\tau)d\tau \to 0$, if $t \to \infty$. Moreover, since both $x_v$ and $x_{v+w}$ are square integrable, also the righthandside of the above equation is square integrable. Now, consider $x_{v+\epsilon w}(t)$. Elementary calculation shows that $x_{v+\epsilon w}(t) = x_{v+w}(t) - (1 - \epsilon)\int_0^t e^{A(t-\tau)}(B_1 B_2)w(\tau)d\tau$. So, using the above result, it is clear that $x_{v+\epsilon w}(t)$ is square integrable. Moreover, since both $v$ and $v + w$ are square integrable it follows that $w$ has to be square integrable too. From this follows then immediately that also $v + \epsilon w$ is square integrable.

Combining both results gives then that $\lim_{t \to \infty} J_i(v + \epsilon w) < \infty$, $i = 1, 2$. Which implies that $v + \epsilon w \in U$. 

Next, we introduce the set of coupled algebraic asymmetric Riccati-type equations associated with this problem:

$$0 = -A^T K_1 - K_1 A - Q_1 + K_1 S_1 K_1 + K_1 S_2 K_2;$$

$$0 = -A^T K_2 - K_2 A - Q_2 + K_2 S_2 K_2 + K_2 S_1 K_1,$$

where $S_i = B_i R_i^{-1} B_i^T$, $i = 1, 2$.

We will see in the next section that the solutions $K_1, K_2$ to this set of equations, that satisfy an additional stability property, play a similar role like the stabilizing solution of the algebraic Riccati equation in the standard LQ regulator problem.

3 The equilibrium strategies

The basic result of this paper is summarized in the next theorem:

Theorem 2:
The two-player linear quadratic differential game (1) has for every initial state an open-loop Nash equilibrium $\left( \begin{array}{c} u_1 \\ u_2 \end{array} \right)$ if and only if there exist $K_1$ and $K_2$ that are solutions
of the algebraic Riccati equations (ARE) satisfying the additional constraint that the eigenvalues of \( A_{ad} := A - S_1K_1 - S_2K_2 \) are all situated in the left half complex plane. In that case, the strategy

\[
u_i(t) = -R_i^{-1}B_i^T K_i x(t), \quad i = 1, 2
\]

is an open-loop Nash equilibrium strategy. Moreover, the costs obtained by using this strategy for the players are

\[
\int_0^\infty \{ (e^{A_{ad}t}x_0)^T (Q_i + K_i^T S_i K_i) e^{A_{ad}t}x_0 dt, \quad i = 1, 2.
\]

Proof:

\( \Leftarrow \) This part was proved by Engwerda (1996), theorem 12.

\( \Rightarrow \) To prove this part we use the variational approach (see e.g. Friedman (1971), Lukes and Russell (1971) and Engwerda (1996)).

Suppose that \( \bar{u}_1, \bar{u}_2 \) are a Nash solution. That is,

\[
J_1(u_1, u_2) \geq J_1(\bar{u}_1, \bar{u}_2) \quad \text{and} \quad J_2(u_1, u_2) \geq J_2(\bar{u}_1, \bar{u}_2).
\]

Then, for any control function \( \left( \begin{array}{c} w \\ 0 \end{array} \right) \) such that \( \left( \begin{array}{c} \bar{u}_1 + w \\ \bar{u}_2 \end{array} \right) \in U \) we have, according lemma 1, that for any real number \( \epsilon \)

\[
J_1(\epsilon) := J_1(\bar{u}_1 + \epsilon w, \bar{u}_2) \geq J_1(\bar{u}_1, \bar{u}_2).
\]

Let \( x_\bar{u}(t) \) and \( x_{\bar{u} + \epsilon w}(t) \) be the solutions to (1) corresponding to the controls \( \left( \begin{array}{c} \bar{u}_1 \\ \bar{u}_2 \end{array} \right) \) and \( \left( \begin{array}{c} \bar{u}_1 + \epsilon w \\ \bar{u}_2 \end{array} \right) \), respectively. Then it is easily verified that (see also proof of lemma 1)

\[
x_{\bar{u} + \epsilon w}(t) = x_\bar{u}(t) + \epsilon g(t),
\]

where \( g(t) := \int_0^t e^{A(t-s)} B_1 w(s) ds \) is a square integrable function. So, \( J_1(\epsilon) \) can be rewritten as:

\[
\frac{1}{2} \int_0^\infty f(t, \epsilon) dt,
\]

where

\[
f(t, \epsilon) := (x_{\bar{u}}(t) + \epsilon g(t))^T Q_1 (x_{\bar{u}}(t) + \epsilon g(t)) +
(\bar{u}_1(t) + \epsilon w(t))^T R_{11} (\bar{u}_1(t) + \epsilon w(t)).
\]

Note that \( f(t, \epsilon) \) is differentiable w.r.t. \( \epsilon \) for every \( t \in (0, \infty) \). Simple calculations show that

\[
\frac{\partial f}{\partial \epsilon} = 2 \epsilon (g^T(t)Q_1 g(t) + w^T(t)R_{11}w(t)) +
2 (g^T(t)Q_1 x_{\bar{u}}(t) + w^T(t)R_{11} \bar{u}_1(t))
\]
Using the facts that $g(t), w(t)$ and $\bar{u}_1(t)$ are square integrable, it is obvious now that $\frac{\partial f}{\partial u_i}$ is integrable for, e.g., all $\epsilon \in [-1, 1]$. Using standard arguments we have then that $J_1(t)$ is differentiable on $(-1,1)$ and that

$$
\begin{align*}
\frac{dJ_1(\epsilon)}{d\epsilon} &= \int_0^\infty \{\epsilon (g^T(t)Q_1 g(t) + w^T(t)R_{11} w(t)) + \\
&\quad (g^T(t)Q_1 x_\bar{a}(t) + w^T(t)R_{11} \bar{u}_1(t))\} dt
\end{align*}
$$

From (5) we get

$$
\frac{dJ_1(\epsilon)}{d\epsilon} \bigg|_{\epsilon = 0} = 0.
$$

So, we get:

$$
\int_0^\infty \{g^T(t)Q_1 x_\bar{a}(t) + w^T(t)R_{11} \bar{u}_1(t)\} dt = 0.
$$

Substitution of the expression for $g(t)$ into this equation and then interchanging the order of integration yields:

$$
\int_0^\infty \{ \int_0^\infty (e^{A(t-s)} B_1 w(s))^T Q_1 x_\bar{a}(t) dt \} ds + \\
\int_0^\infty w^T(t)R_{11} \bar{u}_1(t) dt = 0.
$$

Which can be restated as:

$$
\int_0^\infty \{ w^T(t)B_1^T e^{-A^T t} \int_t^\infty e^{A^T s} Q_1 x_\bar{a}(s) ds \} dt + \\
\int_0^\infty w^T(t)R_{11} \bar{u}_1(t) dt = 0.
$$

Now, choose in the above expression consecutively $w(t) := \text{sgn}[e_1^T (B_1^T \int_0^\infty e^{A^T (s-t)} Q_1 x_\bar{a}(s) ds + R_{11} \bar{u}_1(t))] e^{-\lambda t} e_i, i=1,\ldots,n$, where $\lambda$ is an arbitrary real number larger than the spectral radius of matrix $A$ and $e_i$ is the $i$-th standard basis vector in $\mathbb{R}^n$. Then it is clear that for every choice of $w(t)$, $\bar{u}_1 + w(t) \in U$. Consequently it follows that

$$
\bar{u}_1(t) = -R_{11}^{-1} B_1^T \int_t^\infty e^{A^T (s-t)} Q_1 x_\bar{a}(s) ds.
$$

Similarly, it can be shown that $\bar{u}_2(t)$ necessarily satisfies:

$$
\bar{u}_2(t) = -R_{22}^{-1} B_2^T \int_t^\infty e^{A^T (s-t)} Q_2 x_\bar{a}(s) ds.
$$

Next, we introduce the vector $v := (v_1^T \ v_2^T \ v_3^T)^T$ as follows: $v_1(t) := x_\bar{a}(t), v_2(t) := \int_t^\infty e^{A^T (s-t)} Q_1 x_\bar{a}(s) ds$ and $v_3(t) := \int_t^\infty e^{A^T (s-t)} Q_2 x_\bar{a}(s) ds$. Then $\bar{u}_1 = -R_{11}^{-1} B_1^T v_2(t)$ and $\bar{u}_2 = -R_{22}^{-1} B_2^T v_3(t)$. Moreover, it is easily verified by differentiation of $v_2(t)$ and $v_3(t)$, that $v(t)$ satisfies

$$
\dot{v}(t) = -\begin{pmatrix}
-A & S_1 & S_2 \\
Q_1 & A^T & 0 \\
Q_2 & 0 & A^T \\
\end{pmatrix} v(t), \text{ with } v_1(0) = x_0.
$$
Since by assumption for arbitrary \( x_0, v(t) \) converges to zero, it follows that there exist \( K_1, K_2 \) and a stable matrix \( A \) such that
\[
\begin{bmatrix}
-A & S_1 & S_2 \\
 Q_1 & A^T & 0 \\
 Q_2 & 0 & A^T
\end{bmatrix}
\begin{bmatrix}
I \\
K_1 \\
K_2
\end{bmatrix}
= \begin{bmatrix}
I \\
K_1 \\
K_2
\end{bmatrix} A.
\]

Writing out these equations yields then the advertised result.}

**Remark:**
Parts of the above proof can be substituted by using the results of Haurie et al. (1984, lemma 5.1). This requires, however, the introduction of the concept of weak overtaking optimality. In this framework it is not required that the state or the performance criterion converge (see Halkin (1974)). Since we like to stay in the framework of bounded performance criteria, we choose to give an elementary self-contained proof of the theorem.

In the above theorem the costs for the individual players are expressed as an integral. In fact, analogously to the optimal LQ regulator theory, we have that the costs can be obtained indirectly by solving the following associated Lyapunov equations\(^1\)

\[
A_d^T M_i + M_i A_d + Q_i + K_i^T S_i K_i = 0, \tag{11}
\]

where \( A_d := A - S_1 K_1 - S_2 K_2 \), \( i = 1, 2 \).

Note that if all eigenvalues of \( A_d \) are in the left half complex plane and \( Q_i + K_i^T S_i K_i \geq 0 \), this equation has a unique positive semi-definite solution \( M_i \). The equilibrium costs can then also be obtained as

**Proposition 3:**
Assume that \( K_1, K_2 \) solve (ARE) and satisfy the stabilization property mentioned in theorem 2. Let \( M_i \) be the unique positive semi-definite solution of the above Lyapunov equation (11): Then,

\[
J_i(\bar{u}_1, \bar{u}_2) = x_0^T M_i x_0, \quad i = 1, 2. \tag{12}
\]

**Proof:**
Let \( M_i \geq 0 \) be the unique solution of (11). Then, using the notation \( x(t) := e^{A_{ct}t} x_0 \), we have

\[
J_i(\bar{u}_1, \bar{u}_2) = \int_0^\infty x(t)^T (Q_i + K_i^T S_i K_i) x(t) dt
= \left| \begin{array}{c}
\int_0^\infty x(t)^T (A_d^T M_i + M_i A_d) x(t) dt \\
\int_0^\infty \frac{d}{dt} [x(t)^T M_i x(t)] dt
\end{array} \right|
= x_0^T M_i x_0 - \lim_{t \to \infty} x(t)^T M_i x(t)
= x_0^T M_i x_0.
\]

* I like to thank Arie Weeren for pointing out this to me
which proves the claim.

4 The solutions for the algebraic Riccati equation

In the previous section we saw that we can find all equilibrium solutions by determining all solutions \(K_1, K_2\) of the set of algebraic Riccati equations (ARE), which satisfy the additional property that all eigenvalues of the corresponding matrix \(A - S_1K_1 - S_2K_2\) lie in the left half complex plane.

MacFarlane (1963) and Potter (1966) independently discovered that there exists a relationship between the stabilizing solution of the algebraic Riccati equation and the eigenvectors of a related Hamiltonian matrix in linear quadratic regulator problems. Abou-Kandil et al. (1993) already pointed out the existence of a similar relationship for our problem. One of their results was that if the planning horizon \(t_f\) in (1) tends to infinity, under some technical conditions, the solution of the finite planning horizon problem converges to a solution which requires the calculation of a solution \(K_1, K_2\) of (ARE) which can be calculated from the eigenspaces of the matrix

\[
M := \begin{pmatrix}
-A & S_1 & S_2 \\
Q_1 & A^T & 0 \\
Q_2 & 0 & A^T
\end{pmatrix}.
\]

(13)

In Engwerda et al. (1995) this relationship between solutions of (ARE) and eigenspaces of matrix \(M\) was elaborated. Using the notation \(\mathcal{M}^{\text{inv}}\) for the set of all \(M\)-invariant subspaces, it was shown that all solutions for the set of algebraic Riccati equations can be calculated from the following subset of \(M\)-invariant subspaces:

\[
\mathcal{K}^{\text{pos}} := \{ K \in \mathcal{M}^{\text{inv}} | K \oplus \text{Im} \begin{pmatrix}
0 & 0 \\
I & 0 \\
0 & I
\end{pmatrix} = \mathbb{R}^{3n} \}.
\]

Note that elements in this set \(\mathcal{K}^{\text{pos}}\) can be calculated using the set of matrices

\[
K^{\text{pos}} := \{ K \in \mathbb{R}^{3n \times n} | \text{Im}K \oplus \text{Im} \begin{pmatrix}
0 & 0 \\
I & 0 \\
0 & I
\end{pmatrix} = \mathbb{R}^{3n} \}.
\]

The following result was proved:

Proposition 4:

(ARE) has a real solution \((K_1, K_2)\) if and only if \(K_1 = YX^{-1}\) and \(K_2 = ZX^{-1}\) for some

\[
K =: \text{Im} \begin{pmatrix}
X \\
Y \\
Z
\end{pmatrix} \in \mathcal{K}^{\text{pos}}.
\]

Moreover, if the control functions \(u^*_i(t) = -R_i^{-1}B_i^TK_i\Phi(t)x_0\) are used to control the system (1), the spectrum of the closed-loop matrix \(A - S_1K_1 - S_2K_2\) coincides with
\(\sigma(-M|\kappa)\).

From this result we first of all observe that every element of \(K^{pos}\) defines exactly one solution of (ARE). Furthermore, this set contains only a finite number of elements if and only if the geometric multiplicities of all eigenvalues of \(M\) is one (see e.g. Lancaster and Tismenetsky (1985)). So, in that case we immediately conclude that (ARE) will have at most a finite number of solutions. Furthermore, we see that

Corollary 5:

(ARE) will have a set of solutions \((K_1, K_2)\) stabilizing the closed-loop system matrix \(A - S_1K_1 - S_2K_2\) if and only if there exists an \(M\) invariant subspace \(K\) in \(K^{pos}\) such that \(\text{Re}\ \lambda > 0\) for all \(\lambda \in \sigma(M|\kappa)\).

So, the study of the equilibria of our LQ game boils down to the study of all \(M\) invariant subspaces \(K\) in \(K^{pos}\) for which \(\text{Re}\ \lambda > 0\) for all \(\lambda \in \sigma(M|\kappa)\).

The next example illustrates that in general there may be more than one equilibrium:

Example 6:

In Engwerda et al. (1995) the following example was considered:

\[
A = \begin{pmatrix}
0 & -1 & 0 & -1 \\
0 & 1 & -1 & 0 \\
0 & 0 & 1 & -1 \\
-2 & 0 & 0 & 1
\end{pmatrix}, \quad B_1 = I_4, \quad Q_1 = \text{diag}(3.5, 2, 4, 5), \quad Q_2 = \text{diag}(1.5, 6, 3, 1),
\]

\(R_{11} = I_4, \text{ and } R_{22} = 2I_4\).

By considering the eigenvalues and corresponding eigenspaces of matrix \(M\), it was shown that (ARE) has 7 solutions \(K_1, K_2\) satisfying the stabilization property. So, according to theorem 2, for this choice of matrices, the infinite planning horizon game has 7 open-loop Nash equilibria.

5 Concluding remarks

In this paper we considered the existence of open-loop Nash equilibrium solutions in the two-player infinite-planning horizon linear quadratic game. We derived both necessary and sufficient conditions for existence of such equilibria. Furthermore we showed how these equilibria can be calculated from the invariant subspaces of the Hamiltonian matrix associated with this game \(M = \begin{pmatrix}
-A & S_1 & S_2 \\
Q_1 & A^T & 0 \\
Q_2 & 0 & A^T
\end{pmatrix}\). It turns out that the eigenvalues of the closed-loop system, if the open-loop control strategies are implemented in (1), can be obtained from the eigenvalues of this matrix.

As was illustrated in an example, in general the game will have more than one equilibrium. An important open problem remains the study of the eigenstructure of this matrix.
One property, which was already noted in Engwerda (1996), is that if a discounting factor is included in the performance function that is large enough, matrix $M$ will have $n$ stable eigenvalues. So, in that case there exists at most one equilibrium. Since generically the corresponding eigenvectors will be such that they together form an element of $K_{pos}$, we get generically a unique equilibrium in the discounted case. Moreover, combining the results on scalar systems from Engwerda (1996) and the results of theorem 2, we have that for scalar systems there exists always a unique equilibrium. Finally we note that the obtained results can be straightforwardly generalized to the $N$ player game.

689 G. Facchini, F. van Megen, P. Borm and S. Tijs
   Congestion models and weighted Bayesian potential games
   Communicated by Prof.dr. A.J.J. Talman

690 Jos Grazell en Chris Veld
   Alternatieve Perspectieven in de Theorie van de Ondernemingsfinanciering
   Communicated by Prof.dr. P.W. Moerland

691 Gert Hegge en Rezaul Kabir
   Een nadere analyse van de relaties tussen aandelenrendementen en winsten,
   dividenden en cash-flows
   Communicated by Prof.dr. P.W. Moerland

692 P. Jean-Jacques Herings
   On the Representation of Admissible Rationing Schemes by Rationing Functions
   Communicated by Prof.dr. A.J.J. Talman

693 P. Jean-Jacques Herings
   Rigidity of Prices, the Generic Case?
   Communicated by Prof.dr. A.J.J. Talman

694 Laurence A.G.M. van Lent, Rob C.W. Eken
   Aansprakelijkheid: een teken van kwaliteit
   Communicated by Prof.drs. G.G.M. Bak RA

695 Edwin R. van Dam, Willem H. Haemers
   A characterization of distance-regular graphs with diameter three
   Communicated by Prof.dr. M.H.C. Paardekooper
696 Paul Smit
Generating Identical Ritz Values
Communicated by Prof.dr. M.H.C. Paardekooper

697 Antoon van den Elzen
An adjustment process for the standard Arrow/Debreu model with production
Communicated by Prof.dr. A.J.J. Talman

698 B. Kamp
Study regarding the structural discount of the price of Elsevier stock compared to
the price of Reed stock
Communicated by Drs. P.J.W. Duffhues

699 Edwin R. van Dam
Bounds on separated pairs of subgraphs, eigenvalues and related polynomials
Communicated by Dr.ir. W.H. Haemers

700 Jelmer Boersma en Chris Veld
Het gebruik van financiele derivaten door grote Nederlandse ondernemingen
Communicated by Prof.dr. P.W. Moerland

701 Ad H.J.J. Kolnaar en Pieter J.F.G. Meulendijks
Zijn Cobbenhagen's ideeën opnieuw opnieuw aktueel?
Communicated by Prof.dr. Th. van de Klundert

702 C.L.J.P. van Raalte en H.M. Webers
Spatial competition with intermediated matching
Communicated by Prof.dr. A.J.J. Talman

703 Herbert Hamers en Marco Slikker
The PEGS-rule for probabilistic sequencing situations
Communicated by Prof.dr. S. Tijs

704 Nick van der Lijn
Measuring well-being with social indicators, HDI5, PQLI, and BWI for 133 countries
Communicated by Prof.dr. J. James

705 Nick van der Lijn
Well-being, democracy, and the economic system: an empirical analysis
Communicated by Prof.dr. J. James

706 Jack P.C. Kleijnen
Sensitivity Analysis and Related Analyses: a Survey of Statistical Techniques
Communicated by Dr.Ing. W.J.H. van Groenendaal

707 Aldo de Moor
The Development of a Research Network Information System Specification Method
Communicated by Prof.dr. R.A. Meersman

708 J.J.A. Moors, M.H. Schuld and A.C.A. Mathijsen
A new method for assessing judgmental distributions
Communicated by Prof.dr. B.B. van der Genugten

709 Laurence van Lent
Onderzoek op het gebied van de externe verslaggeving
Communicated by Prof.drs. G.G.M. Bak

710 Josien van Cappelle-Konijnenberg
Restructuring, firm performance and control mechanisms
Communicated by Drs. P.J.W. Duffhues

711 B.B. van der Genugten
Blackjack in Holland Casino’s: basic, optimal and winning strategies
Communicated by Dr. A.M.B. De Waegenaere

712 Prof.dr. F.W. Vlotman
Het vragen naar Toegevoegde Waarde
Communicated by Prof.dr.mr. P.M. v.d. Zanden RA
IN 1996 REEDS VERSCHENEN

713 Jeroen Suijs en Peter Borm
Cooperative games with stochastic payoffs: deterministic equivalents
Communicated by Prof.dr. A.J.J. Talman

714 Herbert Hamers
Generalized Sequencing Games
Communicated by Prof.dr. S.H. Tijs

715 Ursula Glunk en Celeste P.M. Wilderom
Organizational Effectiveness = Corporate Performance?
Why and How Two Research Traditions Need to be Merged
Communicated by Prof.dr. S.W. Douma

716 R.B. Bapat en Stef Tijs
Incidence Matrix Games
Communicated by Prof.dr. A.J.J. Talman

717 J.J.A. Moors, R. Smeets en F.W.M. Boekema
Sampling with probabilities proportional to the variable of interest
Communicated by Prof.dr. B.B. van der Genugten

718 Harry Webers
The Location Model with Reservation Prices
Communicated by Prof.dr. A.J.J. Talman

719 Harry Webers
On the Existence of Unique Equilibria in Location Models
Communicated by Prof.dr. A.J.J. Talman

720 Henk Norde en Stef Tijs
Determinateness of Strategic Games with a Potential
Communicated by Prof.dr. A.J.J. Talman

721 Peter Borm and Ben van der Genugten
On a measure of skill for games with chance elements
Communicated by Prof.dr. E.E.C. van Damme

722 Drs. C.J.C. Ermans RA and Drs. G.W. Hop RA
Financial Disclosure: A Closer Look
Communicated by Prof.drs. G.G.M. Bak RA

723 Edwin R. van Dam & Edward Spence
Small regular graphs with four eigenvalues
Communicated by Dr.ir. W.H. Haemers

724 Paul Smit
Inexact Iterations for the Approximation of Eigenvalues and Eigenvectors
Communicated by Prof.dr. M.H.C. Paardekooper
725 Tammo H.A. Bijmolt, Michel Wedel
A Monte Carlo Evaluation of Maximum Likelihood Multidimensional Scaling Methods
Communicated by Prof.dr. R. Pieters

726 J.C. Engwerda
On the open-loop Nash equilibrium in LQ-games
Communicated by Prof.dr. J.M. Schumacher

727 Jacob C. Engwerda en Rudy C. Douven
A game-theoretic rationale for EMU
Communicated by Prof.dr. J.E.J. Plasmans

728 Willem H. Haemers
Disconnected vertex sets and equidistant code pairs
Communicated by Prof.dr. S. Tijs

729 Dr. J.Ch. Caanen
De toekomst van de reserve assurantie eigen risico
Communicated by Prof.dr. A.C. Rijkers

730 Laurence van Lent
The Economics of an Audit Firm: The Case of KPMG in the Netherlands
Communicated by Prof.drs. G.G.M. Bak RA

731 Richard P.M. Builtjens, Niels G. Noorderhaven
The Influence of National Culture on Strategic Decision Making:
A Case Study of the Philippines

732 S. Tijs, F. Patrone, G. Pieri, A. Torre
On consistent solutions for strategic games
Communicated by Prof.dr. A.J.J. Talman

733 A.J.W. van de Gevel
From Strategic Trade Policy to Strategic Alliances in the Global Semiconductor Industry
Communicated by Prof.dr. A.B.T.M. van Schaik

734 M. Voorneveld, H. Norde
A Characterization of Ordinal Potential Games
Communicated by Prof.dr. S. Tijs

735 J.C. de Vos, B.B. van der Genugten
Fitting a stochastic model for Golden-Ten
Communicated by Dr.ir. A.A.F. van de Ven

736 Gert Nieuwenhuis
Ergodicity Conditions and Cesàro Limit Results for Marked Point Processes
Communicated by Prof.dr. B.B. van der Genugten
P.J.F.G. Meulendijks, D.B.J. Schouten
Dynamiek, Analyse en Politiek
Communicated by Prof.dr. A.H.J.J. Kolnaar

Antoon van den Elzen
Constructive application of the linear tracing procedure to polymatrix games
Communicated by Prof.dr. A.J.J. Talman

René van den Brink
Skewness of the Wage Distribution in a Firm and the Substitutability of Labor Inputs
Communicated by Prof.dr. P.H.M. Ruys

Sharon Schalk
General Equilibrium Model with a Convex Cone as the Set of Commodity Bundles
Communicated by Prof.dr. A.J.J. Talman
