Document Version:
Publisher’s PDF, also known as Version of Record (includes final page, issue and volume numbers)

Please check the document version of this publication:
• A submitted manuscript is the version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher’s website.
• The final author version and the galley proof are versions of the publication after peer review.
• The final published version features the final layout of the paper including the volume, issue and page numbers.

Introduction & Objectives

In past decades, several rapid-prototyping technologies have been developed, stereolithography (SLA) is one of them. Here the liquid starting material is converted into a solid product by light-activated polymerization, see Figure 1 (left).

Unfortunately the final products show poor mechanical performance and shrinkage. The goal of this research is to characterize the mechanical properties of photopolymers. Therefore the first step is to characterize the intrinsic mechanical properties which are representative for one single layer and to determine the influence of UV-curing parameters on the mechanical and thermal properties.

Fabrication of micropillars

A photoinitiator (2,2-Dimethoxy-2-phenylacetophenone) is added to the acrylate monomer (bisphenol-A ethoxylate diacylate) to initiate the photopolymerization. Micrometer-sized cylindrical samples are prepared via UV-curing in a nitrogen atmosphere, see Figure 1 (right). An exposure time of 1.5s for a mixture of 3wt% of initiator is used.

Results

The influence of UV post-curing is studied by observing how the exposure time affects the glass-transition temperature, Tg, and the monomer conversion. The change in Tg, monomer conversion, and the evolution of the absorbance peak at 810 cm⁻¹ (FTIR analysis) are shown in Figure 3.

The intrinsic mechanical properties of the resin are studied, using compression experiments on the NanoIndenterXP. Micro-compression tests on the micropillars with diameter and height of 80 µm are performed for various deformation rates.

Conclusions & Future work

The setup for the sample preparation is built: the wafer and the photomask are aligned in a box under UV light. The box prevents oxygen inhibition by working in nitrogen atmosphere. By varying the process conditions, light intensity and exposure time, it is possible to optimize the sample preparation. So far the evolution with time of Tg and conversion is studied and nano-indentations on maximally post-cured resin are performed. In the next step compression tests on micropillars with different sizes will be performed to investigate if the micropillars show size effects [1].
