Service-Dominant Business Model Design for Digital Innovation in Smart Mobility

Oktay Turetken, Paul Grefen, Rick Gilsing, O. Ege Adali
Eindhoven University of Technology, Eindhoven, The Netherlands

Abstract

In many business domains, we see rapid changes as a consequence of digital innovation, i.e., the application of novel information technologies to achieve specific business goals. A domain where digital innovation has great potential is smart mobility: allowing large sets of people and goods to efficiently move around in a specific geographic setting. So far, many innovations in this domain have concentrated on relatively isolated, technology-driven developments, such as smart route planning for individual travellers. Nice as they are, they have relatively small impact on mobility on the large scale. To achieve large-impact digital innovations – for example optimizing overall commuting on a city-scale – we need to align the efforts and related values of a spectrum of stakeholders that need to collaborate in a common business model. To this aim, this study proposes the use of service-dominant business logic, which emphasizes the interaction of value-network partners as they co-create value through collaborative processes. Moving to this paradigm has significant implications on doing business: the business requirements to services will change faster, and the complexity of value-networks required to meet these requirements will increase further. This requires new approaches to business engineering that are grounded in the premises of service-dominant logic. This paper introduces the service-dominant business model radar (SDBM/R) as an integral component of a business engineering framework. Following a design science approach, the SDBM/R has been developed in close collaboration with industry experts and evaluated through an extensive series of hands-on workshops with industry professionals from several business domains. This paper focuses on the application and evaluation in the smart mobility domain, addressing the design of new business models for digital innovation of collaborative transport of people and goods. In summary, it contributes a novel business design approach that has an academic background and relevant practical embedding.

Keywords: Digital innovation, service-dominant, business model, service business model, business network, value-in-use, value co-creation, smart mobility.

1 Introduction

In many contemporary business domains, customers desire integrated solutions for their needs, instead of products that they have to deploy themselves to fulfil these needs (Vargo and Lusch 2004). In an example business-to-consumer domain, we see that customers move from buying traditional music playing devices (goods) to getting subscriptions to full-fledged music streaming services (solutions). In a business-to-business setting, we see, for example, that companies move away from buying transportation vehicles, and instead employ integrated logistics solutions. Consequently, many organizations are transitioning towards a service-dominant (SD) business setting, where the provisioning of solution-oriented services to the customers is the focal point (Lusch and Vargo 2006). This moves away from the traditional goods-dominant setting where the emphasis is on the delivery of products (Ostrom et al. 2010). The services may require the deployment of products, but these products become part of the delivery channel of services, not the central point. Ownership of the products becomes a less relevant issue. This transition has shifted the emphasis from the value of the individual products or services to the value of the use of the products and services in an integrated,
customer-focused context, so-called value-in-use (Lusch and Vargo 2008) or value-in-context (Vargo 2009).

In the smart mobility domain, the shift to the service-dominant business is prominent. This domain is currently experiencing a strong move from an emphasis on individual vehicles and infrastructure (i.e., a goods-dominant perspective) to an emphasis on integrated services delivering a true value-in-use to end users (i.e., a service-dominant perspective). A good example in transport of people is the shift from individual ownership of cars to advanced, service-based automotive ecosystems. To illustrate, a recent global survey of KPMG states that 85% of almost 1,000 interviewed senior executives from the world’s leading automotive companies agree that digital ecosystems will generate higher revenues than the hardware of cars itself (KPMG 2017). To provide complex services, there is a strong necessity for digital ecosystems to manage the flood of information associated with these services. In other words, business model innovation goes hand-in-hand with digital innovation (Legner et al. 2017).

In the transport of goods, we see comparable examples; instead of offering vehicles for transportation, logistics providers have started offering integrated, end-to-end logistics solutions involving multiple actors that have complex, data-driven interactions. Digital innovation is an enabler of value creation in logistics (Rai et al. 2012). In general, digital innovation is a major force for business innovation (Barrett et al. 2015), which is often driven by increasing focus on customer experience and expectations (Abrell et al. 2016; vom Brocke 2016). The conclusion of this is that the smart mobility domain provides ample opportunities for the exploitation of a service-dominant mindset with large-scale digital innovations (Böhmann et al. 2014).

The underlying digital technology in the mobility domain is referred to as C-ITS (cooperative intelligent transport systems) (Alam et al. 2016). Business-oriented layers need to be added on top of technology layers to support the viability of applying the technology in practice (EC: C-ITS Deployment Platform 2016). In this domain, we see many small-scale digital innovations with a technology-push character. Many C-ITS applications or services, such as green-light optimal speed advice (GLOSA), green priority, probe vehicle data, or road-side networks (Mitsakis et al. 2014) emerge due to increasing technological capabilities. However, these digital technologies rarely offer a value to the end-user in isolation and hence have very limited impact in mobility practice. The end-user value is created by composing them into complex digital innovations involving many building blocks, including other digital technologies. Such complex innovations, on the other hand, are hard to realize as they rely on multi-stakeholder collaboration in a real-time and data-driven context.

The delivery of these complex digital innovations requires an agile integration of the capabilities of multiple service providers and introduces the necessity of tightly managed business networks (Camarinha-Matos and Afsarmanesh 2005). Organizations no longer operate in isolation, but they collaborate in a network to deliver complex solutions (Gawer and Cusumano 2008). This requires new approaches to business model design that are grounded in the premises of service-dominant (SD) logic.

There is an increasing attention for the concept of business models in academic literature (Schneider and Spieth 2013; Massa et al. 2016). Several works investigate and propose approaches for defining and representing business models (Gordijn and Akkermans 2001; Osterwalder and Pigneur 2010; Veit et al. 2014; Roelems and Poels 2015). Although many of these approaches consider cross-organizational relations and the importance of partnerships, they are typically characterised by being organization-centric and hence reason from the perspective of a single focal company (Zolnowski et al. 2014; Turber et al. 2015).

However, given the solution-oriented nature of SD logic, a business model design approach for service-dominant business must adopt a network-centric mind-set at its core and allow for the composition of service design in multi-party business networks, which also includes the customer as a co-creator of the value (Turber et al. 2014; Lusch and Nambisan 2015). Such an approach defines how actors in the business ecosystem participate in value co-creation and what the cost–benefits distribution in the
network is. It operationalizes the business strategy and provides a starting point for a mapping to the operational processes and organizational capabilities. It also facilitates the level of business agility required to operate in service-dominant markets.

Therefore, the research objective of our work is to develop a new approach for collaborative business modelling that satisfies the aforementioned requirements of service-dominant business. Accordingly, we have developed the service-dominant business model radar (SDBM/R) as an integral part of our business engineering framework. SDBM/R is a visual template for representing service-dominant business models. At the centre of the template is the value-in-use, which represents the added value of a service-based solution to be realized by a network of organizations for a specific customer group. The other elements of the template include the value proposition, co-production activities, and the associated cost/benefit items for each of the involved organizations in the network. Together with its method of use, SDBM/R guides the collaborative development of service-dominant business models.

Following the design science research (DSR) methodology (Hevner et al. 2004), we developed the initial version of the SDBM/R by taking related works in the literature as a basis, but developing a new concept specifically targeted at the collaborative, agile nature of SD logic. The initial versions of the artefact were refined through a joint effort with industry experts using focus-groups and workshops. Further, we evaluated the SDBM/R for its validity and utility. For evaluating validity, we organized a series of workshops, where a large number of industry professionals used the SDBM/R to collectively design new service-dominant business models in the mobility domain, in particular for solutions that address urban mobility challenges of a number of European cities. To evaluate the utility of the SDBM/R and its method of use, we performed a survey with the participants of the workshops. Our evaluation through the workshops and survey shows that SDBM/R can be considered useful for the collaborative design of service-dominant business models in the mobility domain.

The SDBM/R and its method of use aims at bridging the world of technology-push building block digital innovations (e.g., C-ITS services) and the world of requirements-pull (customer-focused) digital innovations that are complex in nature. As such, the SDBM/R is a DSR-based artefact that is not a digital innovation per se but is used as an essential component in the generation of real-world digital innovations in any data-driven, real-world business situation. The SDBM/R -when used effectively-leads to the generation of digital innovations that have actual impact.

The remainder of this paper is structured as follows. In Section 2, we provide a background on the key concepts of service-dominant business and discuss related work on the business model design. Section 3 presents the research design that we followed in constructing, applying and evaluating the SDBM/R approach. Section 4 introduces the SDBM/R and how it can be used in practice. In Section 5, we present the application of the SDBM/R in the workshops that we organized with industry professionals. Here, we have the focus on the smart mobility domain and the combined role of services and digital innovation. In section 6, we present and discuss the results of the survey conducted with the workshop participants. Finally, Section 7 presents our conclusions and future research directions.

2 Background and Related Work

In this section, we first review the paradigm shift from goods-dominant to service-dominant business and discuss related literature on the conceptualization and design of business models. Secondly, we provide a background on the business engineering framework in which the SDBM/R approach that we introduce in this paper is integrated.

2.1 Service-Dominant Business

In early 1990s, manufacturing companies recognised that their traditional value-chain role of producing and selling goods became less profitable, and that they have to move beyond the factory gate to get closer to the customer and towards providing services required to operate and maintain
products (Wise and Baumgartner 1999). The product’s role started to be seen as a mechanism for service delivery.

This shift to services is a move from the means and the producer perspective to the utilization and the customer perspective. Customers buy offerings which render services that create value (Gummesson 1995). Innovating a value is considered as a collaborative process occurring in an actor-to-actor network. It is not developed within the confines of a single organization; instead, it evolves from the joint action of a network of actors including suppliers, partners and customers – so called the ‘value network’ (Chesbrough 2003; Lusch and Nambisan 2015). Co-creation of value is grounded on the fundamental idea of SD logic, which argues that humans apply their competences to benefit others and reciprocally benefit from others’ applied competences through service-for-service exchange (Vargo and Lusch 2004).

Although SD logic is introduced mainly by marketing scholars, it has a major role in driving service business design and operation, which remains largely unexplored in academic literature (Ostrom et al. 2010; Grönroos and Gummerus 2014). Transitioning to service-oriented business requires agility not only at the level of business models, but also in the business operations and supporting IT systems. At the same time, it calls for a tight integration between the two sides of business: what services to offer and how to get them delivered (Magretta 2002). Performing this transition and managing its consequences is a formidable task for any non-trivial business organization.

2.2 Business Model Design and Service-Dominant Logic

Early works provided diverse interpretations and definitions of the business model, focussing primarily on its conceptualization (Osterwalder and Pigneur; Timmers 1998; Amit and Zott 2001; Gordijn and Akkermans 2001; Chesbrough 2003; Shafer et al. 2005; Massa et al. 2016) and its relationships with IS (Hedman and Kalling 2003). Later works aimed at consolidating interpretations to offer a better understanding of the concept and facilitating the process of business model design (Osterwalder and Pigneur 2010; Al-Debei and Avison 2010; Zott et al. 2011; Veit et al. 2014; Roelens and Poels 2015). Al-Debei et al. (2010) defines a business model as the way in which an organization -along with its providers and partners- creates value for all its stakeholders. Taking a broader perspective, Magretta (2002) views a business model as a story that explains how an enterprise works. Well-designed business models that ensure harmonization among business strategy, processes, and information systems are crucial for any organization to survive and succeed (Magretta 2002; Di Valentin et al. 2012).

Business model representations have been in the form of a mixture of informal texts and graphical representations (Zott et al. 2011). Gordijn and Akkermans (2001) propose an ontology (e3-value ontology) that borrows concepts from the business literature. It uses a network-centric approach to model constellations of enterprises and end-consumers who create, distribute, and consume things of economic value. An e3-value model describes the value exchanges among actors of a business network. However, it emphasizes on the analysis of business models’ economic feasibility through the value exchanges among actors of a business network (rather than the conceptual definition of business models and the value-in-use). The relationships between the actors in the network are mapped bilaterally, as opposed to the multilateral nature of the value-network in SD business.

Following the precedent set by Gordijn and Akkermans (2001), Osterwalder and Pigneur (2002) proposed the Business Model Ontology (BMO) that formed the basis for the development of the Business Model Canvas (BMC). The BMC is a visual chart with elements describing a company’s or product’s value proposition, customers, infrastructure including its partnerships, and financial aspects. It has been widely adopted in practice for designing business models (Osterwalder and Pigneur 2010). However, it follows an organization-centric approach that renders the model from the perspective of a single company, as opposed to a network-centric view (Turber et al. 2015). It focuses on the processes controlled by the focal company and pays less attention on the customers’ active role in value co-creation.
Adopting an organization-centric approach in business model design is a manifestation of the Goods-Dominant (GD) logic and its underlying assumption regarding the creation of value (Luftenegger et al. 2015). The organization-centric approaches adapt the value chain perspective where the firm creates goods, and pushes them out to its customers, who are then responsible for using them to fulfill only part of their needs. Value is produced at the left-side of the chain and consumed at the right-hand side. The value-network perspective of the SD logic, instead, supports value co-creation by a network of parties, which also includes the customer: the network as a whole creates the integrated solution that the customer needs (Lusch and Nambisan 2015). A product in the GD logic is assumed to be valuable of itself, whereas in the SD logic, it has no value unless the customer uses it (Parker et al. 2016).

With the increasing importance of services, there has been an emergence of a number of business modelling approaches that explicitly focus on services and reflects its networked view [e.g., (Bouwman et al. 2008; Heikkila et al. 2008; Turber et al. 2014; Zolnowski and Böhmann 2014)]. The STOF framework (Bouwman et al. 2008) incorporates the service, technology, organization and finance dimensions of business models, and emphasizes on the network-based creation of value. The CSOFT ontology (Heikkila et al. 2008) is built upon the same dimensions, with explicit emphasis on the customer relationship. However, these approaches do not explicitly consider the role of the customer as the co-creator of the value-in-use. These frameworks take a wider perspective in business modelling (as opposed to focusing on the essential elements) and includes aspects regarding the operationalization and implementation of the solution (De Vos and Haaker 2008). Instead of a single representation for the business model, STOF incorporates a series of representations for different business model dimensions with varying degrees of details, for instance for the technical architecture of the solution, which can pose difficulties in the ease-of-use and adoption of the method by practitioners with limited experience in business model design.

The works by (Zolnowski et al. 2014) and (Turber et al. 2014) propose representations for business models in service-dominant business, and as such offers contributions that are closer to the work presented in this paper. Zolnowski et al. (2014) introduce the Service Business Model Canvas (SBMC) which offers a representation with a stack of multiple BMCs each allotted for a specific network party, including the customer. The SBMC addresses majority of the principles of SD logic. However, the SBDC does not explicitly take the value-in-use as a starting point for the business model. It inherits the use of the concept of value-proposition, but considers it as a value that the focal organization offers to customers and other partners through the business model. This notion does not follow the SD principles of value co-creation and reflects the GD logic rooted in the BMC. Incorporating multiple customer segments in a single representation increases the complexity of the representation, and makes it also difficult to reflect and communicate the process-oriented view of the service solution depicted in a business model.

Another approach that aims at the design of service-dominant business models is the framework proposed by Turber et al. (Turber et al. 2014, 2015). The framework specifically targets at the business models in the Internet of Things (IoT) context and features 3 dimensions: business network (including the customer as a co-creator of value), cost-benefit structures (for each party), and the sources of value co-creation with respect to the architectural layers of digitized objects. Although the framework has been designed to fulfil the particular requirements posed by the SD logic, the specific lens that it incorporates into its core design to cater for the IoT-driven environment makes it less capable in representing business models in other contexts. Furthermore, the framework is still in the early phases of development and requires applications in real-life business settings to evaluate its effectiveness.

In brief, although the existing approaches to business model ontologies and design provide the basis for the key elements that constitute a business model, the mainstream approaches to business model design fall short in addressing the premises of the SD logic, in particular the focus on the value-in-use, the basis in a value network, the role of the customer as a co-creator in this network, and the process-oriented nature of the SDBM.
2.3 Business Engineering Framework

A solution-oriented service provider is concerned not only about what services to offer, but also about how to get them delivered. Managing service complexity and business agility requires a tight integration between the business strategy and business models on the one hand, and the structure of business operation and information technology on the other hand (Al-Debei et al. 2008). Truly agile service provisioning business is not achievable if these elements are treated in isolation.

Our previous work has introduced the essentials of a business engineering framework that puts forward the structural elements for performing service-dominant business (Grefen et al. 2013; Luftenegger 2014; Grefen and Turetken 2018). The framework (so called, BASE/X) is tuned to the essentials of SD logic (Lusch and Vargo 2008; Vargo and Lusch 2008) and is built on the existing works on business design and engineering (Osterwalder and Pigneur; Sanz et al. 2007; Al-Debei et al. 2008; De Castro et al. 2009; Al-Debei and Avison 2010).

The framework adapts a holistic view and covers the entire spectrum from high-level business strategy definition to business information system architecture design. It distinguishes between the business goals (the ‘what’ of business) and business operations (the ‘how’ of business) on the one hand, and between the relatively stable essence of an organization (business strategy and business services) and its agile market offerings (business models and service compositions) on the other hand. This leads to a model with four layers, as shown in Figure 1.

The first layer, business strategy, describes the identity of an organization in a service-dominant market (Karpen et al. 2012; Luftenegger et al. 2015). The strategy is relatively stable over time: it evolves. The second layer contains service-dominant business models, describing market offering in the form of integrated solution-oriented complex services. They follow fluid market dynamics and are agile: they revolve – they are conceived, modified, and discarded as required. Business models are specialized from the strategy as they implement part of the strategy in a more specific way. They are operationalizations of the strategy as they are more concrete.

The bottom half of the pyramid covers business operations engineering, which contains business services and service compositions. Each business service encloses a core service capability of the organization. As these capabilities are related to the resources, they are relatively stable over time: they evolve. In the service compositions layer, business services are composed to realize the service functionality required by a business model: they implement a concrete value-in-use. A composition, in the form of a business process model, includes business services from the organization’s own set, but also business services of partner organizations in the value-network (Welke 2015). As service compositions follow business models, they are agile: they revolve with their associated business models.

The framework makes an explicit distinction between the stable essence of a business organization (strategy and business services) and the agile market offerings of that organization (business models and service compositions).

![Figure 1 Business Pyramid](image-url)
and service compositions) (Massa et al. 2016). This distinction between the stable and agile aspects is important as digital transformation requires more agility and improved responsiveness (Mingay and Mesaglio 2016). As shown in Figure 2, engineering the stable part of business takes place in the strategic design cycle. In this cycle, the identity and the capabilities of an organization are aligned in an evolutionary fashion. Engineering the agile part of business takes place in the tactic design cycle. Here, business models and their realization in service compositions are created, modified and discarded in a revolutionary fashion. The tactic design cycle ‘spins’ at a higher speed than the strategic design cycle. This fast-paced nature of the tactic design cycle supports managing uncertainty, which is foundational to success in the digital era. Digitalization often needs adaptive approaches to implementing change, which can be contrasted to the traditional, predictive methods of implementing change (Mingay and Mesaglio 2016).

Alignment of both cycles takes place by confronting business goals between strategy and business models, and by confronting business means between business services and service compositions (as shown in Figure 2). This alignment realizes the necessary co-engineering of stable and agile business elements.

In (Luftenegger et al. 2015) we address the need to translate the principles of SD logic into actionable insights for practitioners at the strategic level, where the focus is on the conceptualization, formulation, and communication of a service-dominant business strategy.

This study focuses on the second layer of the framework: Business Models. Being an integral part of the framework puts additional requirements on its design to reflect its relationship with other layers of the framework. The next section describes these requirements as a part of the overall research process that we followed in developing the SDBM/R.

3 Research Design

As we introduced above, the objective of our research is to develop the SDBM/R – a visual template to represent service-dominant business models, which depicts the way that a network of organizations co-creates a value for a specific customer group through a solution-oriented service and generates revenue and benefits for all network parties. This paper elaborates on the design and development of the SDBM/R and its method of use, with special focus on its extensive application and evaluation in the smart mobility domain.

In developing the SDBM/R, we have followed a design science research (DSR) methodology (Hevner et al. 2004; Gregor and Hevner 2013), as our primary goal is to develop a new IS artefact. Accordingly, our approach involved identifying the problem, defining requirements of the solution, designing and
developing a satisfactory model, applying the model in a suitable context, and the evaluation of the artefact in a real-life business setting to examine its validity and utility (Peffers et al. 2006; Baskerville et al. 2009).

We followed the process depicted in Figure 3 in developing the SDBM/R. After identifying the problem through our interactions with practitioners and review of relevant literature, we iteratively defined the requirements that our solution artefact (radar) should fulfil. Based on these requirements and insights from the review of existing literature, we developed the initial version of the SDBM/R.

Next, we performed two rounds of focus group meetings with 11 industry professionals to gather their feedback about the initial version, after which we refined the SDBM/R to increase its relevancy and applicability. Following the refinement, we used the SDBM/R and followed its method of use in 3 workshops, where practitioners applied the refined version of the radar to design business models in the smart mobility domain (more specifically, traffic management). The focus groups and application of the SDBM/R in these initial series of workshops can be considered as a light-weight (ex-ante) evaluation of the artefact to demonstrate that it feasibly works (Venable et al. 2012). The feedback gathered in these steps were helpful in refining and finalizing the artefact (including its requirements) and ensuring its content validity.

The last two steps in the research process took the final version of the artefact and aimed at its application (demonstration) and ex-post evaluation (Venable et al. 2016). This involved a series of workshops where the artefact was used by practitioners in the smart mobility domains to design innovative business models with an SD logic in mind. We organized 15 workshops -in total with 161 professionals- to evaluate the validity of the artefact (i.e., the extent to which it is applicable and can be used for its intended purpose of use (Gregor and Hevner 2013)). Next, we conducted a survey with the participants of the workshops (among which 58 participants responded) to evaluate the utility of
the SDBM/R, i.e., how useful and easy-to-use they consider the artefact is in designing service-dominant business models.

The following subsections describe the details about the steps that were carried out, including the research methods applied in developing the SDBM/R. We discuss the details regarding the evaluation of SDBM/R and its method of use in Section 6 (after introducing the artefact and the example models emerged from its application in Section 4 and 5, respectively).

Different versions of the artefact, and our intermediate experiences in their application and evaluation, as well as the resulting models that have been developed using our artefact, have been communicated with practitioners and scholars through a number of technical reports (Traganos et al. 2015; Grefen et al. 2016; Turetken and Grefen 2016; Turetken et al. 2018) and conference papers (Luftenegger et al. 2013; Grefen et al. 2015; Turetken and Grefen 2017). This paper sheds light on the complete research process that we went through and brings together the overall experience with additional focus and insight gained from its extensive application in the smart mobility domain.

3.1 Problem Identification

In the first section of this paper, we provide an extensive discussion of the problem and research gap that our study aims to address. This step included our recognition of this problem and research gap through several interactions with companies, and our review of the existing literature on business models and SD logic.

3.2 Defining Requirements of the Solution

The requirements for our solution artefact are driven by the core principles of SD logic (Lusch and Vargo 2008). At the forefront of these principles is the emphasis on the service as a fundamental basis of exchange and consideration of products as the distribution mechanisms for services (Vargo and Lusch 2004). The focus is on the value-in-use (or value-in-context); that is, the value that the customer will get when the product is used in a particular context (Vargo 2009). Accordingly, the first requirement can be stated as follows:

- R1: The artefact should support taking the value-in-use as a point of departure for the design of an SDBM.

The second core principle is the network centric view in business model design. Delivering complex and integrated solution to a customer requires a network of basic business service providers (Lusch et al. 2007; Gawer and Cusumano 2008). Therefore, we state the following requirement:

- R2: The artefact should support taking a business network perspective to reflect multi-party collaboration in an SDBM.

Another aspect in the SD logic is the perspective on the role of the customer. It considers the customer as an indispensable part in the value creation process and an essential party in the co-creation of value (Lusch and Nambisan 2015). The following requirement reflects this standpoint:

- R3: The artefact should support expressing the customer as a co-creator of the value-in-use.

Each party should justify its partaking in the network with a unique value it offers as a part of the co-created value-in-use. A party joins in the network and offers this value due to some benefits it expects (Lusch et al. 2007). These benefits (and costs) can be not only in monetary but also in nonmonetary forms. Accordingly, we can state the following requirements:

- R4: The artefact should support specifying the value propositions for each network party.
- R5: The artefact should support specifying the benefits and costs in monetary and nonmonetary forms for each network party.

Unlike the case in the goods-dominant logic, a service solution in the SD logic is process oriented (Vargo and Lusch 2004). The unique value that is contributed by a party (R4) is realized by an activity
performed by that party. This activity and the effects that it creates is observable by the customer. These properties create the need to specify the activities that each network performs to realize its share of value-in-use, and to describe the way the customer experiences the creation and delivery of value-in-use (Suratno et al. 2018). The customer experience is a key input to the operationalization of business models in the form of service compositions. Accordingly, the following requirements can be stated:

- **R6**: The artefact should support specifying the activities that each actor performs in the business for achieving the co-creation of value.
- **R7**: The artefact should support describing the customer experience in the form of a brief description of how the customer will interact with the service solution to deliver the value-in-use.

In addition to these functional requirements listed above, we require our artefact to be considered *useful* and *easy-to-use* by its users, as it is designed for use by industry professionals, practitioners in various domains, possibly with limited experience in business model design. The artefact should allow for reaching at a *quick* blueprint design of the business model, focusing only on the essential elements, to support communicating the idea within and outside the network and facilitating rapid and timely decision making.

These requirements collectively portray the central term in this study — i.e., service-dominant business model (SDBM). We can define the SDBM as a *representation of the way in which a network of organizations, including the providers and customer, co-creates a value for the customer through a solution-oriented service and generates revenue and benefits for all network partners.*

### 3.3 Developing the initial version of the SDBM/R

We developed an initial version of the SDBM/R by taking as a ground the requirements that we defined for our artefact in the previous step, and the existing works on business model design and ontologies. In particular, we confronted the Business Model Canvas (BMC) (Osterwalder and Pigneur 2010) against the service-dominant mind-set (Luftenegger 2014). We chose BMC as a base due its strong academic foundation and high relevance to business practitioners. However, the BMC is a firm-centric model and embeds a value chain (rather than a value network perspective) over business model design. It identifies suppliers and clients at different ends of the value chain, and their role in generating costs and revenues for the focal organization. This contradicts with the requirements of our artefact as listed above. Accordingly, we conceptualize the service dominant business model as a collection of *actors* (i.e. heterogeneous entities such as businesses, firms, and customers), which interact with each other to achieve shared goals, i.e. *value co-creation*. These entities can be viewed as socio-economic actors, connected through *value propositions*. They perform actions aimed at reaching desired outcomes, such as mutual value creation through co-produced solutions and experiences (Wieland et al. 2012). Each actor has an active role in the business model through *co-production activities*, which eventually incur costs and benefits for each one. We elaborate on these concepts more in Section 4, when discussing the finalized artefact.

### 3.4 Focus Groups

To increase the relevancy of the SDBM/R to practice, we organized two rounds of focus group meetings with industry experts. The selection of focus group as a research method was mainly due to the efficiency it offers in interviewing several participants at the same time and allowing in-depth discussions in the meetings (Kontio et al. 2004). The focus group comprised 11 executives and business-unit managers of a large enterprise that offers financial services to companies operating in diverse domains. The participants had over 7 years of experience on the average (the most experienced with 15 years of experience and the least with 5) in management, strategy definition, and business model design in the leasing/financial sector. The primary goal in these one-hour meetings was to capture the shortcomings of the initial version of the SDBM/R by focusing on its understandability and applicability in practice. In each meeting, the facilitator (one of the authors of
this paper) presented the initial version of the SDBM/R by going through an illustrative scenario. The participants provided in-depth review and feedback on the elements of the SDBM/R focusing on its understandability and pragmatic use, which led to changes and simplifications in the key elements of the radar. The initial and intermediate versions of the SDBM/R are available in (Luftenegger 2014).

3.5 Smart mobility business modelling workshops (ex-ante)

The next step in the research process was to provide a setting for industry practitioners to use the improved version of the SDBM/R in designing new business models. We selected traffic management (a related domain in the smart mobility) as a suitable business domain to apply the SDBM/R for designing innovative business models (as discussed later in this paper in section 5). We organized 3 workshops for the design of three SDBM/R blueprints and were able to bring together industry experts representing in total 20 stakeholder firms operating in the traffic management, mobility, and interrelated domains (including event organizers, retailers, etc.). In the first part of the workshops, we presented the principles of the SD logic, and introduced the SDBM/R. In the second part, the authors of this paper moderated sessions where the participants collaboratively designed service-dominant business models using SDBM/R around a specific business theme (e.g., traffic management in a certain district of a city during large events).

We gathered feedback from participants about the elements and use of the SDBM/R, as well as its potential benefits. During the workshops, we focused mainly on the method of use – i.e., the SDBM design method, but also received improvement suggestions for the elements of the radar. An example of such a suggestion involves the representation of cost-benefit flow between actors in the SDBM/R, which was incorporated in the final edition of the radar as an optional layer in the representation. The feedback gathered through the focus groups and workshops were helpful in finalizing the SDBM/R and its method of use and ensuring the content validity and practical relevance.

4 SDBM Radar and its Method of Use

In this section, we present the final version of the SDBM/R resulting from the focus group meetings and workshops and describe how it can be effectively used for collaborative design of service-dominant business models.

4.1 Elements of the SDBM Radar

Figure 4 presents the elements of the SDBM/R. The co-created value-in-use constitutes the central point in SDBM/R (fulfilling R1 as presented in Section 3.2). Following service-dominant thinking, it represents the value of a solution to a customer. It is not a service delivering the value, nor a product used to produce or transfer the value.

The first concentric layer framing the value-in-use contains the actor value propositions, which represent the part of the central value-in-use contributed by a single actor (R4). The co-production activity defines the activities that each actor performs in the business for achieving the co-creation of value, i.e. its actor value proposition (R6). The effects of this activity are observable by the customer.
Figure 4 Service Dominant Business Model Radar (SDBM/R) template

The third frame—actor cost/benefits—defines the financial (monetary) and non-financial expenses/gains of the co-creation actors. Finally, each ‘pie slice’ of the radar represents a co-creation actor, including the focal organization, core and enriching partners, and the customer. We put the labels of the actors in the fourth frame. The focal organization is often the party that initiates the setup of the business model and participates actively in the solution. The customer is always one of the parties contributing to the production of the value-in-use ($R_3$). A core partner contributes actively to the essentials of the solution, while an enriching partner enhances solution’s added value-in-use. SDBM/R accommodates an arbitrary number of actors, suiting the network-centric character of service-dominant business ($R_2$).

All parties— including the customer, collaborate such that each of them has a clear interest in the business model. Collaboration is on the basis of mutual ethical benefit in terms of the SD logic. More concretely, a business model is set up to bring benefits to all parties, but also incurs costs to all parties. These benefits and costs can be of financial or non-financial character ($R_3$). This calls for bi-directional collaboration between actors rather than an outsourcing relation, which implies a client/server relation with typically opposite interests.

A business model defines a concrete value-in-use for a concrete customer segment – and in its realization, i.e., the way the customer experiences the creation and delivery of this value-in-use. Therefore, a business model may take an informal scenario as a basis for inspiration, which is refined during the design process into a description of a customer experience (Bitner et al. 2008). The customer experience offers a brief description for the high-level operation and future realization of the business model ($R_7$).

4.2 Using the SDBM Radar

The business model design using the SDBM/R involves the following design steps:

1. Identifying and agreeing on the co-created value-in-use and the targeted customer (or customer-segment). The value-in-use is the added value of a solution for the customer, who also contributes to its creation.
2. Description of the customer experience typically starts at this stage and runs in parallel with the design of the radar, often in verbal form and with several iterations, until the radar is considered complete.

3. Determining the components of the value-in-use (actor value propositions) and associated actors (roles). One actor is the focal organization, often taking the role of orchestrator. The number of actors is arbitrary, but it is a good practice to focus on the core actors at the initial stages of the design to reflect only the essence of the model. More information on the background of the concept of actors and their roles in the business model is available in (Luftenegger 2014).

4. Determining the costs and benefits for each actor. These can be of a financial or a non-financial character. A cost item of an actor typically relates to a benefit, often with another actor(s). An optional practice at this step is to define the cost/benefit flow among actors. (In the SDBM/R this is shown either using color codes or arrows between costs and benefits, positioned in a separate circular frame in-between the cost-benefit frame.) This flow also provides an input for the customer experience mentioned above. The sum of costs and benefits for each actor -in a qualitative sense- is expected to be positive. Similarly, the business model as a whole should have a positive sum of costs and benefits from a global perspective (in qualitative terms).

5. Determining for each actor, the high-level activities that realize the actor-value proposition. These activities become a part of the customer experience and can be mapped -at a later stage- to (sequences of) tasks in business processes executed by the parties in the network.

Despite the sequential design steps described above, the business model design using SDBM/R should be applied as an iterative process. The application of the radar during our workshops showed that, the activities performed in step 3, i.e., determining costs and benefits, and their flow among actors, have high potential to influence the decisions given in prior steps. A typical course of sequence during and after this step is to revisit the actors and their roles, as well as their value propositions as depicted in the radar to ensure alignment between the radar and the customer experience that the actors agreed on. The outcome of this practice is a business model depicted in a radar together with the customer experience, which can be expressed textually as a story, or graphically as a story board.

A practical setup for the business model design involves a number of stakeholders brought together around a theme in a business model design session, which is moderated by a person experienced in the use of SDBM/R. The moderator should foster out-of-the-box thinking while engaging the stakeholders in active communication and collaboration for innovative ideas.

5 Using SDBM/R to address Mobility Challenges

In this section, we describe the particular context in which we applied/demonstrated the use of the SDBM/R. We start with a discussion of the need for service-dominant business models in the mobility domain. Next, we present the workshops that we conducted for the design of business models to address the mobility challenges of a number of European cities. Finally, we give examples of two SDBMs that were collaboratively designed in these workshops.

5.1 The Need for Service-Dominant Business Models in the Mobility Domain

Increasing population and urbanization bring major challenges in cities. According to United Nations (2014), the percentage of the world’s population residing in urban areas is expected to increase from 54% (in 2014) to 66% by 2050. Given the increasing population, this will be a significant rise that would intensify the existing problems and mobility challenges of urban areas.

The mobility and related domains, such as traffic management, and transportation, have been confronted with a strong shift of emphasis to the provisioning of customer-focused services to end users. These domains have been traditionally characterized by their focus on product innovations and
developments. The focus in innovation has been typically on developing and realizing new assets such as roads, traffic detection systems, road signage, and cooperative intelligent transport systems (C-ITS). However, this asset-dominant orientation has two main drawbacks.

Firstly, the assets are typically very costly to develop and deploy, which means that they must be designed for strategic, long-term use. This long-term approach is, however, hard to combine with much faster changing user requirements, which are strongly related to emerging transport patterns. Organizations developing or deploying the assets observe the situation from their own, isolated perspective.

Secondly, the end users of mobility solutions are not interested in the characteristics of the individual assets, but in the added value that the use of combinations of assets brings to them (Bruns and Jacob 2014). As an example, car drivers are not so much interested in algorithms that determine traffic information on roadside signage, but in travel time reduction that they may realize by any means of traffic management.

The fact that there are multiple groups of end users (private drivers, professional drivers, institutions that need to remain accessible, the city that wants to uphold a good image) with complex network of interactions puts further challenges in developing a business case for the deployment of these assets. When deployed effectively, C-ITS and related technology is expected to offer significant contributions to a cleaner, safer and more efficient mobility (EU Parliament 2010; EC: C-ITS Deployment Platform 2016).

The abovementioned drawbacks play a key role in the slow and fragmented deployment of related technologies and inhibit their potential to bring about the expected benefits (Asselin-Miller et al. 2016; EC: C-ITS Deployment Platform 2016). The research on the business model perspective of mobility and intelligent transportation systems is limited. Given that the cities are often challenged to cover the intensive investments for infrastructure and service delivery, the work on the business model aspects of the mobility domain has a strong practical relevance in the mobility ecosystem. There is a need for innovative business models for large-scale deployments of mobility solutions to address the urban mobility challenges and advance the value that can be reaped from the use of related technology and infrastructure (Cohen and Kietzmann 2014; Angelidou et al. 2015).

Mobility is a promising field with significant opportunities for the exploitation of service-dominant mindset (Böhmann et al. 2014). Therefore, the use of a collaborative business model design approach with an explicit focus on the value delivery to the customer and that takes into account the multi-stakeholder nature of the domain can offer significant benefits. Therefore, we address the confluence of service-dominant business and digital innovation in the design and evaluation of the SDBM/R in the smart mobility domain.

5.2 Application of the SDBM/R in Business Model Design Workshops

To address the urban mobility challenges faced in a number of European cities, we organized a series of business model design workshops with the participation of industry professionals working in organizations operating in the mobility and related domains. We organized 15 workshops between June 2015 and June 2018, where we asked participants to collaboratively design new business models for mobility solutions that target at the particular mobility challenges faced by specific user groups. Table 1 lists these workshops, the business models that were designed, the time-location information about the workshops, and the number of participants in each workshop. In total, we were able to bring together 161 practitioners collaboratively designing blueprints for 21 new business models.

**Table 1** The service-dominant business model design workshops conducted in the mobility domain

Figure 5 shows further demographics of the participants regarding their experience in the domain, and the size of the companies that they work for. Majority of the participants were experienced professionals working in the mobility and related domains for more than 10 years (Figure 5a), while they varied in terms of the time they had been working in their current position (Figure 5b).

The companies that the participants represented were of diverse size (Figure 5c). Accordingly, there was a balance in terms of the size of the companies and in the number of SMEs and large enterprises. The companies also varied considerably in terms of type. They included private companies (such as mobility service/technology providers, telecom/mobile network operators, parking operators, etc.), and public organizations (such as municipalities, road authorities, traffic managers, public transport operators, etc.), as well as those that are of public-private partnership or of non-profit type (such as automobile/motorcycle clubs, cycling associations, etc.). This helped us to elicit viewpoints of different business stakeholders in the domain.
In our survey, we also asked participants to indicate their familiarity with business model design. Figure 5d shows the distribution over the set of participants\(^1\). Accordingly, the participants varied also with respect to the knowledge/experience on business modeling. The group involved participants who considered themselves quite experienced, and those who had very limited knowledge on business model design.

Authors of this paper participated in all workshops, one of whom acted as the moderator in each session (alternatingly). Each meeting was organized as a 2-hour workshop with two phases. The first phase involved a tutorial on the concept of service-dominant business, business engineering framework, and the use of SDBM/R. The second phase comprised the core of the collaborative design of a business model using the SDBM/R. Following a practical approach, large SDBM/R template posters and ‘post-its’ were used to represent the SDBM/R blueprints and its specific elements (as exemplified in the section below).

The blueprints for the business models shown in Table 1 are publicly available in a series of (technical) reports, catalogued as those relate to the people mobility (Traganos et al. 2015; Grefen et al. 2016; Turetken et al. 2018) and others to the goods mobility (Turetken and Grefen 2016). In the next subsection, we give examples of two service-dominant business models that were collaboratively designed in our workshops and target at specific urban mobility challenges of two European cities.

\(^1\) Please note that, this question was incorporated late in our series of workshops. As a result, the graph (Figure 5d) is based only on the responses of 20 participants.
5.3 Examples of Innovative Business Models in the Smart Mobility Domain

In this section, we provide two examples of new business models in the smart mobility domain, which are the basis for the practical introduction of digital innovation in traffic management. The first business model given as an example aims at addressing heavy traffic in South-East Amsterdam, particularly due to large events. The second model aims at aiding cities in their efforts to reduce car traffic in city centres. Note that, although these blueprint business models emerged from the particular context in these cities that led to the related mobility challenges, they can be used and concretized for other cities facing similar mobility challenges.

Free-Ride Amsterdam Event

Like most large cities, Amsterdam is characterized by heavy traffic, which worsens during daily rush hours, but reaches its worst peak when large events are held in the southeast part of the city. Events, such as football matches and concerts (and even the combination), attract large volumes of traffic in a narrow time-window. Locations to accommodate such large events are clustered the South-East Amsterdam, which consequently meets these traffic problems at a regular pace. To try and counter these problems collaboratively, we arranged a business model design workshop within the scope of a project with the participation of a large variety of stakeholders, both of the public, the private and the individual kind. The public kind included the city of Amsterdam, the province of North-Holland and the Dutch road authority. The private kind included several event locations in the southeast section of the city, organizers of events at these locations, local retailers, parking providers, and transport providers. The individual kind was formed by individual road users, both car drivers and other users influenced by car traffic.

Figure 6b depicts the completed SDBM/R blueprint for the business model.

Figure 6 The picture on the left (a) shows the use of the SDBM/R poster and 'post-it's during the workshop. The figure on the right (b) shows the business model blueprint in SDBM/R for Free-Ride Amsterdam Event.
The Free-Ride Amsterdam Event value-in-use contributes to the positive experience of event visitors who plan their arrival by car. The idea behind the model is to attract visitors at a much earlier time than the beginning of the event, which helps reduce the traffic just before the event. This is facilitated by offering free parking, funded by parties benefiting from the early presence of the visitors (such as retailers). A number of stakeholders in the network contributes to this service. The Mobility Broker acts as the focal organization orchestrating the parties. The Parking Provider provides parking services for an easy car disposal, while the Road Authority provides the road infrastructure and traffic management before and after the event for a reliable and safe trip. Retailers are also involved by contributing to customer’s experience with pre- and post-event convenience (shopping, eating, etc.). Following the SDBM/R method of use depicted in Section 4, the collaborative business model design session led to the design of the model depicted in Figure 6b.

Green and Comfortable Commuting to Inner-city Bordeaux

Heavy traffic is a problem also in Bordeaux, particularly in the old city-centre, which has reached its peak utilization of its transport infrastructure and resources, while it is still being challenged with increasing car traffic to and from its commuter belt, and demand for more parking space. The municipality initiates programs to improve city traffic through measures for reducing car traffic in the centre and endorsing public transportation. In our business model design workshop in Bordeaux, we targeted at this challenge and designed a business model taking the inner-city commuter as our customer who travels by car often on a daily basis.

Figure 7 presents the essential components of the business model blueprint that emerged from the workshop. The objective is to provide a setting with incentives for the commuters to make a model shift from driving to public transportation when approaching to the dense inner-city. The commuter is endorsed to park outside the inner-city and take public transport to the final travel destination.

The solution is supported by a number of C-ITS (cooperative-intelligent transportation system) services (Alam et al. 2016), including urban-parking availability (Kaplan et al. 2006) and mode and time trip advice (Capato et al. 2016) offered to the commuter, and green (light) priority (Mitsakis et al. 2014) applied for public transportation vehicles. Urban parking availability provides parking information to its users to make informed decisions about available parking places. The service (to be implemented as a smartphone application or on an on-board-unit within the vehicle) offers an optimal advice to the user about the nearest available parking space, in order to minimize the search for a suitable parking location. Coupled with the parking availability service, is the mode and trip time advice service, which aims to provide a traveller with an itinerary for a multimodal transport journey, taking into account real-time information about options of different modes. In addition to these services provided to the driver, the green priority service aims to change the traffic signals status in the path of a designated vehicle – in this case public transportation vehicles – in order to help reduce their travel time. The service is offered by the traffic manager, where vehicles request priority for an intersection, and the traffic light controller determines in what way it can and will respond to the request.
When traveling from the commuter belt, the solution directs *commuters by car* to the nearest suitable parking location just outside the inner city, taking into account dynamic parking, user, traffic and public transport data. Consequently, mode and trip time advice is offered to facilitate commuters to travel onwards to their desired travel destination. As an incentive, public transport tickets are offered through the application for free or with reduced tariffs, depending on the current traffic conditions in inner-city. As unnecessary cruising for parking is reduced, commuters benefit from increased comfort. Moreover, travelling costs can be reduced as tickets can be offered for free. The *municipality* in turn benefit from decreased pollution, less congestion and therefore an increased attractiveness of the city itself.

The business model is complemented by the transit operator (i.e., public transportation provider), and the road operator (and traffic manager). The transit operator relocates commuters from the parking places to the vicinity of their final destination. The road operator compliments the added value by using the green priority service for public transportation vehicles. It provides the parking information and benefits from a better usable road system at the cost of managing or operating the road infrastructure.

The participants of the workshop also designed different variants of the business model with the inclusion of other enriching parties. For instance, as the commuters’ timeliness potentially improves, certain employers (companies) located in the inner-city can also be included in the network to cover (part of) the service fee. This can be attractive particularly for those companies that are expected to offer parking facilities to employees. Consequently, employers can benefit from green-image and on-time personnel (and can potentially be subsidized for this behaviour). Another variant includes a mobility as a service (MaaS) provider that offers relocation through other means (e.g., private taxis) as opposed to public transportation.
6 Evaluating the Utility of SDBM/R through Surveys

Although SDBM Radar has been developed as a joint effort of experts through focus groups and workshops, it should be applied and evaluated in real-life business settings (Hevner et al. 2004). As mentioned in Section 3, for the evaluation of SDBM/R’s, we focused on its validity and utility. The workshops (that we described above in Section 5) aimed at evaluating the validity, and provided the setting where industry professionals experienced the use of the radar to design new business models, and observed the extent to which the SDBM/R is applicable and can be used for its intended purpose of use. For SDBM/R’s utility, we conducted a survey among the participants who used the SDBM/R to elicit their views on its usefulness and its ease of use as a tool to design service-dominant business models.

6.1 Survey material

After each workshop session, workshop participants were asked to fill out a survey questionnaire in a single paper format to gather their view on the utility of the SDBM/R. Out of 161 workshop attendants, 58 participated in the post-workshop surveys, leading to a participation rate of 36%.

The survey questionnaire was built using a set of statements from the Technology Acceptance Model – TAM (Davis 1989; Venkatesh and Davis 2000). TAM and its derivatives - e.g., (Venkatesh et al. 2003) - are the most commonly referred theories that predict and explain the acceptance of design artefacts, mainly through their perceived usefulness/utility and ease-of-use. It has been used as a theoretical basis for many empirical studies in the information systems field, including the acceptance of IS methods and models (Moody 2003). The original TAM has three primary constructs: perceived ease of use, perceived usefulness, and intention to use (Davis 1989). Perceived usefulness refers to users’ perception on the utility of the design artefact in providing gains to its user (Venkatesh et al. 2003). Perceived ease of use refers to “the degree to which a person believes that using a particular design artefact will be free from physical or mental effort”. Finally, intention to use can be defined as the extent to which a person intends to use a particular design artefact. Intension to use is the most proximal antecedent to the artefact use and believed to be determined by perceived usefulness and ease of use.

All constructs of TAM are operationalised using multiple indicators, which have been rigorously evaluated for reliability and validity (Davis 1989). Following the work in (Venkatesh and Davis 2000), we used 4 items for perceived usefulness and ease of use, and 2 for intention to use. In line with the approach followed in (Moody 2003), the wording of the items was modified to accommodate this research. The participant could express their level of agreement with each statement on a 5-point Likert scale, ranging from 1 (strongly disagree) to 5 (strongly agree).

In addition to questions regarding demographics of the participants, our survey included open-ended questions in order to gather more information about participants’ experience and view on the use of the method. These questions inquired participants to indicate their opinion on the strong and weak points of the approach, the difficulties that they have experienced in the use of it, and the aspects that can be improved. The questionnaire is given in Appendix A.

6.2 Results and Discussion

Using the SDBM/R, the practitioners that participated in the workshops were able to design a considerable number of service-dominant business model blueprints in the smart mobility domain (as listed in Table 1), many of which aim to address specific urban mobility challenges of their regions or cities. These business models and the feedback that we gathered from the participants during the workshops and through the open questions in the questionnaire are valuable to assess the validity of our approach. Respondents agreed that following an explicit method that structures the interactive design of service-dominant business models fostered the creation of innovative ideas. Participants indicated SDBM/R as an effective means for a diverse set of stakeholders to collaboratively design
new business models. The emphasis on designing a business ecosystem with multiple stakeholders (as opposed to an organization-centric approach) was considered as a key point. Taking the customer and value-in-use as a starting point, being able to reflect the networked nature of business, explicit focus on both monetary and non-monetary cost/benefit items for all parties, and the way this information is visualized were considered as strong points of the approach. The respondents further agreed that the use of the approach created awareness on the value of agile, SD business thinking and provided inspiration for collaboration with different stakeholders. Below are two (literally translated) quotes from the participants of the workshops:

"The approach appealed to me and I think it offers leads to further shape our projects and improve our stakeholder analysis."

"An inspiring session. After our investigation of traffic flows, one should sit together (again) with business and government organizations to conceive a business model for a service."

The participants also mentioned a number of difficulties in the use of the approach and points for improvement. Some of these points were related also to the specific business model that they designed. Examples include the difficulty in deciding on the customer, in identifying core and enriching partners, as well as in identifying the core value-in-use for the business model without sufficiently embracing the SD mind-set and being experienced with its principles and terminology. Difficulties also emerged with regard to the different nature of cost/benefit items for each partner (e.g., monetary and non-monetary) and how this challenges the viability/feasibility evaluation of the business model. Early evaluations were considered key in making strategic decisions about whether engaging into the business is worthy. The role of the moderator and his/her level of experience not only in conducting and moderating such events but also in applying and communicating SD logic were also indicated as key factors for the successful use of the approach.

Figure 8 presents the responses for each item in the TAM-based questions of the survey. The results suggest a positive view on all measured constructs, i.e., the perceived usefulness, perceived ease of use and intention to use. All workshop participants considered the SDBM/R to be useful (Q4). Majority of them believed that it would be easy for them to learn and become skilful at using the radar and its design method (Q5, and Q7). Only a single participant indicated an overall negative view on the ease of use of the radar and the method (Q8) and intention to use it (Q9). Overall, the responses of the participants for the model indicate a general positive attitude towards using the radar.

7 Conclusions

The ongoing shift from goods-dominant logic to service-dominant logic has transformed the landscape of business innovation (Lusch and Nambisan 2015) – in many domains like smart mobility. We have experienced breakthrough innovations of intangible nature, which have focused on the development of new processes co-created with all actors (Prahalad and Ramaswamy 2004). These shifts have also expanded the role of information technology as a key facilitator in making innovations technically feasible and economically viable (Veit et al. 2014; Peters et al. 2016). However, in many business domains, the firms’ agility in providing support for such innovations is heavily constrained by the business structures and IT platforms they use to deliver their services. This suggests the need for the development of new frameworks to structure service-dominant business modelling that can aid in integrating business strategy and business models on one hand, and business services, processes, and IT platforms on the other hand, thereby facilitating viability of large-scale business innovations based on contemporary digital technologies.

Our prior work proposed a business engineering framework to assist companies in establishing a basis for structural agility and in instituting a service-dominant business environment. In this paper, we describe an integral part of this framework – i.e. the service-dominant business model radar (SDBM/R) and its method of use, for collaboratively designing business models. We designed SDBM/R as a key component in the generation of complex digital innovations in a multi-stakeholder business environment. Such complex digital innovations often leverage multiple product-based digital technologies together with various capabilities of multiple parties to offer value to a customer in a particular context.

We brought together a diverse set of stakeholders and supported them in collaboratively designing new business models targeting at today’s urban mobility challenges. Collaborative workshops have shown to be effective means to quickly arrive at agile, customer-centric business models. The feedback gathered from the workshop participants and the result of the survey confirm the utility of the model and its potential to be adopted in practice. Our application of SDBM/R in these workshops in the smart mobility domain showed that SDBM/R can be effective in the generation of ideas for digital innovations that have actual impact.

7.1 Contributions to Research and Practice

This work contributes to the research on business models by integrating the concepts related to the core elements and design of business models with the principles of SD business. It provides a concrete basis for researchers and practitioners who aim to apply business modelling concepts to engineer SD business and generate digital innovations enabled by multiple stakeholders. Combined with our prior work on the SD strategy (Luftenegger et al. 2015), this work offers the foundation for structuring the business goals, and initial steps to aligning them to the business operations and implementation of SD business through the application of advanced digital technology. Using business models as a conceptual tool of alignment is significant, since in most of the existing alignment research, this issue is addressed only at the strategic level (Al-Debei and Avison 2010).

The SDBM/R is a practical visual template that can help executives in start-ups or SMEs in designing and communicating their new solutions to the market. The executives in established companies will also find it useful in rethinking their business models and transitioning from a GD to SD business. The business model blueprints presented in this paper and reported in other sources (Traganos et al. 2015; Grefen et al. 2016; Turetken and Grefen 2016; Turetken et al. 2018) target specifically at mobility challenges of a number of European cities. However, these challenges represent a common set that can inspire and act as a point of departure for concrete business models in other urban areas facing similar challenges.
7.2 Limitations and Future Work

Several practitioners have applied SDBM/R and evaluated its usefulness in designing new business models in workshop settings. However, as a limitation of this work, the implementation of many of these models is still ongoing (at the time of writing this paper). However, there are several (independent) initiatives by the companies participated in our workshops where the SDBM/R is used as the starting point in designing new market offerings. For instance, currently one of these companies - an information logistics company in a large international port - has adopted the proposed business engineering approach (that also includes SDBM/R) to designing a service-dominant future for its business. In addition, the SDBM/R has been adopted by six European Consortia working in the area of mobility (C-ITS, automated driving), smart manufacturing, and logistics-transportation for designing and implementing new business models. The SDBM/R has also been introduced on a national scale in The Netherlands by the authorities as the approach to inspire the stakeholders in the mobility and traffic management domain in exploring new collaborative business thinking.

We consider business model innovation as a leverage to process innovation. Consequently, our future work will have a major focus on operationalizing service-dominant business models through service-compositions to support business processes. These compositions will combine a number of (business) services offered by the parties in the business network and can be executed in process-oriented information systems to realize the value proposition. This also requires advanced approaches for effective portfolio management of these (business) services. Our future work will also consider the development of structured approaches for evaluating the viability of service-dominant business models taking both monetary and nonmonetary items into consideration.

Acknowledgments

This work is partially supported by C-MobILE (Accelerating C-ITS Mobility Innovation and depLoymen in Europe) project funded by the European Union’s Horizon 2020 Research and Innovation Programme under Grant Agreement No 723311. The authors especially thank the workshop participants including C-MobILE consortium partners for their participation. The authors also thank Egon Luftenegger and Marco Comuzzi for their contributions to the development of the business engineering framework.
Appendix A: The Questionnaire

PART-1: Please provide feedback about the business model design approach followed during the workshop. *(For all items using the following Likert scale: Strongly disagree; Disagree; Neutral; Agree; Strongly agree)*

Q1. I think this approach provides an effective solution to the problem of designing business models.
Q2. Business models designed in this way would be difficult for users (colleagues, partner companies, etc.) to understand.
Q3. Using this approach would make it more difficult to communicate the business models to others.
Q4. Overall, I found the business model design approach in this workshop to be useful.
Q5. Learning to use this way of designing business models would be easy for me.
Q6. I found the way the business models are designed as unclear and difficult to understand.
Q7. It would be easy for me to become skilful at using this way of designing business models.
Q8. Overall, I found this way of designing business models difficult to use.
Q9. I would use this method to design business models.
Q10. I would intend to use this way of designing business models in preference to another design approach if I have to design business models in the future.

PART-2 *(Respondent demographics)*

Q11. What is your current position?
Q12. How long have you been working in this position? *(Less than 2 years, 2-4 years, 4-7 years, 7-10 years, More than 10 years)*
Q13. How long have you been working in the industry? *(Less than 2 years, 2-4 years, 4-7 years, 7-10 years, More than 10 years)*
Q14. In which industry the company you work in operates?
Q15. What is the size of your company? *(Options for Q15: Below 10 employees, 11-50 employees, 51-250 employees, 251-1000 employees, 1001-5000 employees, Over 5000 employees)*
Q16. How familiar are you in using any technique or approach in designing business models? *(Options for Q16: Not at all familiar, Slightly familiar, Somewhat familiar, Moderately familiar, Extremely familiar)*

PART 3: *(Feedback)*

Q17. Please indicate what you would consider the strong points of the Service-Dominant Business Model Radar approach.
Q18. Please indicate what you would consider the weak points or points that can be improved about the Service-Dominant Business Model Radar approach.
Q19. Any additional remark?
