3D Test: No Longer a Bottleneck!

By Erik Jan Marinissen – imec, Leuven (Belgium)

When I joined imec in October 2008 to work on test and design-for-test (DfT) of 3D-stacked integrated circuits (ICs), there were only a few test folks active in that emerging field. Consequently, misconceptions about 3D test were omnipresent. In the November 18, 2008 issue of Semiconductor International, Alexander Braun wrote: “At a symposium yesterday on 3-D Integration, leading expert Philip Garrou detailed the rise of the technology as well as the challenges facing it, including test, yield, and design. (…) Test, again, will be a significant problem. Memory can be stacked as known good die, because the memory chips can be tested, but years from now, as different functions are pulled apart to stack them, there is no clear way to test them because they do not form a complete circuit. This will hold up things like the full partitioning of chips.”

3D InCites’ tenth anniversary is a good occasion to report on the state of 3D testing and publicly declare that it’s no longer a bottleneck for 3D integration.

Structural Modular Test

‘Test’ is an overloaded term. While some people might think of design verification (on a simulation model) or design validation (on the real chip), this article is restricted to electrical testing for manufacturing defects, typically in a high-volume setting. At this stage of product development, we assume chip designs are correct. Chip manufacturing processes are defect prone as they consist of large numbers of high-precision steps. Unavoidably things go wrong every now and then, leading to spot defects such as shorts and opens.

For a large chip manufactured using advanced technology, the die yield might be 80%, while customers typically tolerate defective chips in quantities of no more than 100 defective parts per million (dppm). Consequently, a test needs to be a very effective filter for defective chips. Because every transistor or interconnect segment on a chip can suffer from defects, each chip needs to be tested, and hence the test needs to be very efficient; taking no more than a few seconds per chip in a fully automated process.

During test, stimuli are fed into the chip and corresponding responses on the chip outputs are compared to expected responses to determine ‘pass’ or ‘fail’. Automatic test pattern generation (ATPG) tools, available from all major EDA suppliers, try to cover as many potential fault locations as possible with a minimum of test patterns to reduce test time and associated cost.

ATPG tools do not utilize application knowledge of the device-under-test (DUT), but instead base themselves on the DUT’s structure: the gate-level netlist with interconnected library-cell instances (AND, OR, flip-flop, etc.). The resulting test patterns have no relation with the mission-mode (‘functional’) operation of the chip, but check if these cells are present, operational, and correctly interconnected. We refer to this as a structural test (as opposed to a functional test).

For a structural test, testing a single die that only implements a partial function of a multi-die stack is no problem at all. This modular approach to test development and execution has become common practice in the industry.

Today’s core-based system-on-chips (SOCs) are routinely tested in a modular fashion: core-by-core, sequentially, or at the same time. For 3D integrated circuits (3D ICs), for which the various stacked dies might be designed and/or manufactured by different parties, modular testing (here: die-by-die) makes even more sense. The benefits include:

![Figure 1a: Example test flow for n=3: maximal 11 die tests and 5 interconnect tests. Figure 1b: Equations for t(n) as function of the number of dies in the stack n. Figure 1c: Number of test t(n), for increasing number of stacked dies n. Figure 1d: Number of alternative test flows f(n), for increasing number of stacked dies n.](image-url)
• Targeted test pattern generation, tailored to the circuit type (e.g., logic or memory) and function, preferably by the team also responsible for the design
• Freedom to (re-)schedule the various die tests if manufacturing yields so require (test engineers like to put tests that are more likely to fail early in their test suite, to reduce the per-die average test time by applying 'abort-on-fail')
• Re-use of tests in case design modules are reused
• First-order fault diagnosis and yield attribution (because: if the test for a particular module fails, that module most likely contains the root cause)

**Test Flow Optimization**

A major difference between testing 2D and 3D ICs is the potential complexity of the test flow. At which moments in the manufacturing flow do we execute a test for what stack component? Conventional 2D chips typically have two test moments: first while still in their wafer (wafer test, a.k.a. e-sort), to avoid package costs for defective dies, and then again after assembly and packaging (final test), to guarantee the outgoing product quality toward the customer. 3D ICs have many more test moments, tests, and hence test flows. For an n-die stack, we have prior to stack assembly n possible test moments during which we can execute a pre-bond test on a die. After every stack assembly operation, we have a new test moment, in which each die and interconnect layer in the stack built up so far can be tested. We refer to these test moments as mid-bond tests (for partial stacks) and post-bond tests (for complete stacks). There are \( \sum_{i=2}^{n} (i) \) die tests and \( \sum_{i=2}^{n} (i-1) \) interconnect tests possible during these test moments. After packaging, the final test can contain n-die tests and (n-1) interconnect tests. In total, an n-die stack has 2n test moments during which a grand total of 2n-1+ \( \sum_{i=2}^{n} (i) \) die tests and n-1+\( \sum_{i=2}^{n} (i-1) \) interconnect tests might occur. In practice, there might be no physical test access during certain test moments, which reduces the number of feasible tests. A test flow consists of an execution decision (yes/no) for each test at each feasible test moment. If a die stack has a total of \( f(n) \) tests, this allows for \( f(n) = 2^{\frac{n(n+1)}{2}} \) alternative test flows. Note: this definition of \( f(n) \) does not account for alternative test schedules due to reordering of tests at a particular test moment.

Figure 1(a) illustrates the test flows for a relatively simple stack with only three dies, resulting in 16 tests (11 die + 5 interconnect tests), and therefore a total of 216 = 65,536 alternative test flows.

In practice, some test moments might not permit probe access, and this reduces the number of feasible tests and test flows. For example, for imec’s FC-FOWLP test chip consisting of seven dies, from the theoretical 68 tests only 33 tests are practically feasible; which still implies a whopping \( 2^{33} \approx 8.6 \times 10^9 \) alternative test flows.

Figure 1(b) shows the generic equations for \( t(n) \) as function of the number of stacked dies \( n \). Figures 1(c) and 1(d) depict \( f(n) \) respectively as function of the number \( n \) of stacked dies.\(^3\)

The large numbers of alternative test flows necessitate computer support. The 3D-COSTAR software tool, developed by TUDelft and imec, makes a cost analysis of a user-specified manufacturing and test flow.\(^3\) The tool considers costs proper to design, as well as five manufacturing operations:

1. Wafer processing
2. Stack assembly
3. Test
4. Packaging
5. Logistics

These operations are considered not perfect and are modeled with an associated yield in percent. For test, ‘yield’ is defined as 100% minus the test escape rate (in dppm). 3D-COSTAR calculates the lump-sum costs per operation, where all costs are attributed to those stacks that pass the entire flow and are shipped to the customer. The tool can analyze the effect of varying

an arbitrary number of parameters (in lock-step) along one or two independent axes, as variations of a user-defined base case. The output of the analyses is an estimation of product quality (defective chips that nevertheless pass the test, in dppm) and the cost per shipped stack, sub-divided over the subsequent manufacturing operations.

Test Access

The main challenges of 3D testing are related to test access: delivering test stimuli to where they can detect the presence of a defect, and the test responses in the opposite direction. Test access comprises two components: external test access, i.e., from the test equipment to the chip I/Os and back, and internal test access, i.e., from the chip inputs to the actual on-die defect location and back to the chip outputs.

With external test access, several challenges and their solutions related to probing on ‘naked’ (= not-yet-packaged) dies or die stacks are described below. Internal test access is handled by on-chip DfT hardware. The conventional (‘2D’) DfT has been extended with 3D-specific features, and those are described at the end of this article.

Probing Challenges and Solutions

For most product scenarios, realistic yields require a combination of pre-bond, mid-bond, and post-bond testing. This prevents manufacturing defects from being discovered too late in the stack-assembly flow thus requiring the entire stack to be scrapped, including perhaps other (defect-free) dies. Whereas test access contact for final test is made through a test socket, the pre-, mid-, and post-bond tests all depend on probe technology. For multi-die stacks, the following probing challenges have been identified and resolved in collaboration with our partners.

Probing on large tape frames.

Stack-assembly flows for multi-die stacks frequently use tape frames as a temporary carrier: for diced wafers, for aggressively thinned-down wafers, for pick-n-placed dies and die stacks, etc. Out of necessity, a tape frame is larger than the wafer it holds; for a ø300mm wafer, the outer dimension of the frame is ø400mm.

Imec worked with Cascade Microtech (now FormFactor) to specify and implement adaptations to the CM300 probe station, so that ø300mm wafers on a large tape frame can be loaded manually. The Tokyo Electron WDF™-12DP probe stations even have an automatic loader for such large tape frames.

Probing ultra-thin wafers on a flexible tape.

Wafer thinning is commonly performed on dies used in multi-die stacks: from 780µm down to ~200µm to fit the stacked dies into a standard-height package cavity or, when TSVs are employed, even thinner to expose the TSVs at the wafer back-side (at imec: 50µm). Stretched UV-curable dicing tape, laminated over a tape frame, is commonly used as a temporary carrier to prevent ultra-thin wafers from sagging and curling.

The forces exercised by probe needles should be sufficiently high to guarantee an acceptable low contact resistance between each probe tip and its corresponding probe pad. However, when we do this on an ultra-thin and flexible wafer atop flexible dicing tape, we should avoid probe forces that cause permanent or even temporary stress-induced electrical or mechanical effects and damage.

At imec, we have done numerous experiments with probe cards that require different probe forces: conventional cantilever, FormFactor’s...
Probing large arrays of fine-pitch micro-bumps.

The interconnect between stacked dies consists of large arrays (>1,000) of Cu and Sn micro-bumps at ultra-fine pitch: 40µm. Imec has developed a unique test system to characterize probe cards that claim to be capable of probing such micro-bump arrays. It consists of a FormFactor CM300 probe station with hard-docking National Instruments test head with 1,216 parametric tester channels.8

Imec has in-house manufactured test wafers with only micro-bumps (>10 million micro-bumps at 40µm pitch on a ø300mm wafer) in various metallurgies. This set-up has been successfully used to characterize advanced micro-bump probe cards which imec co-developed with leading suppliers: FormFactor’s Pyramid® RBI and Technoprobe’s TPEG™ T40.10, 11

Probing singulated dies and die stacks on a flexible tape.

The challenge is that the probe targets might have translated or rotated from their original wafer-map position, such that blind index stepping by the probe station is no longer possible. This happens when probing on diced wafers or diced stacks on dicing tape, due to the flex-n-stretch forces of the dicing tape). Another application is pick-and-place of die-to-die stacks on a carrier substrate, as the pick-and-place tool might be insufficiently accurate for subsequent probing.8 Together with our partner FormFactor, we have developed and successfully demonstrated software that determines the individual misalignment per die or die stack at the start of the wafer probe session and then compensates for it while probing.8

Originally deemed impossible when we started to work on this topic in 2011, today imec is probing 40µm-pitch micro-bump arrays on a rou-
test access mechanism that offers higher bandwidth compared to the one-bit (‘serial’) mandatory part of P1838.20

**Conclusion**

DfT and test engineers know the limits of their work. Our industry is not making chips because the test community has developed a fancy test solution for them; customers would not care. They are interested in more performance, more storage capacity, and higher bandwidth, benefits which can be achieved with 3D ICs. But, on the other hand, our industry cannot put high volumes of products with wonderful new performance/storage/bandwidth features on the market, if these products are not individually tested for defects. Customers do not accept that.

The mere fact that the test community started working on 3D ICs was a clear sign that release of actual 3D products was imminent. With the solutions described in this article, most of the test challenges related to 3D ICs have been addressed, such that we can conclude that ‘test’ is no longer a bottleneck for market introduction of 3D ICs. The test community has delivered, adequately and, while the first products are hitting the market, just on time!

If you want to read more about 3D (test) challenges and solutions: they are described in detail in the book “Design, Test, and Thermal Management”, edited by Paul D. Franzon (NCSU), Erik Jan Marinissen (imec), and Muhannad S. Bakir (Georgia Institute of Technology).

---

**WDF™ 12DP+**

300mm wafer dicing frame prober

**Features**

- Fully automatic dicing frame and standard wafer handling
- Change Over Kit to easily switch between 300mm and 200mm
- “N-Shot” alignment for high accuracy, parallelism probing for diced wafer
- Improved system cleanliness and ESD*
- TEL standard prober application software “PSAS”

**Applications**

- Post dicing test for KGD*, RMA*
- Advanced package test capability (WLP, FOWLP, panel level package)
- Test for thin wafer, multiple PCB, strip frames on dicing frames

*ESD: Electro Static Discharge  
*KGD: Known Good Die  
*RMA: Return Merchandise Authorization
Erik Jan Marinissen is principal scientist at imec in Leuven, Belgium, the world-leading independent R&D center in nanoelectronics technology. His research on IC test and design-for-test covers topics as diverse as 3D-stacked ICs, CMOS below 10nm, silicon photonics, and STT-MRAMs. Marinissen is also visiting researcher at Eindhoven University of Technology in the Netherlands. Previously, Marinissen worked at NXP Semiconductors and Philips Research in Eindhoven, Nijmegen, and Sunnyvale.

Marinissen is (co-)author of 250+ journal and conference papers (h-index: 43) and (co-)inventor of 18 patent families. He has received numerous awards for his work and is very involved in IEEE conferences and standards. Among them, he served as editor-in-chief of IEEE Std 1500 and as founder/chair (currently vice-chair) of the IEEE Std P1838 Working Group on 3D-SiC test access.

Acknowledgments

I thank many colleagues and partners for their fruitful cooperation: Alkis Hatzopoulos, Leonidas Katselas (Aristotle Univ. of Thessaloniki), Teresa McLaurin (Arm), Vivek Chickermane, Brion Keller, Christos Papameletis (Cadence Design Systems), Tobias Burgherr (FHNW), Eric Hill, Jörg Kiesewetter, Ken Smith (FormFactor), Sandeep Bhatia (Google), Pieter Bex, Eric Beyne, Bart De Wachter, Ferenc Fodor, Mario Konijnbenburg, Arnita Podpod, Michele Stucchi (imec), Yu Li, Ming Shao (KU Leuven), Chun-Chuan Chi (NTHU), Adam Cron (Synopsys), Daniele Acconcia, Raffaele Valauri (Technoprobe), Paul Mooney, Eric Pradel, Yoichi Shimizu (Tokyo Electron), Sandeep K. Goel (TSMC), Sergej Deutsch (TU Braunschweig), Said Hamdoui, Motta Taouil, Jouke Verbree (TU Delft), Hailong Jiao (TU Eindhoven), Konstantin Shibin (TU Tallinn), and Michael Wahl (Univ. Siegen).

Part of this work was performed in the project ESIP, “Efficient Silicon Multi-Chip System-in-Package Integration – Reliability, Failure Analysis and Test”, funded by the ENIAC Joint Undertaking (http://www.eniac.eu). This project was winner of the ENIAC Innovation Award 2013. Part of this work was performed in the project SEA4KET, “Semiconductor Equipment Assessment for Key-Enabling Technologies” (http://www.sea4ket.eu), sub-project 3DIMS, 3D Integrated Measurement System, which received funding from the European Union’s Seventh Programme for research, technological development, and demonstration under grant agreement No. IST-611332.

Awards Related to This Work

Erik Jan Marinissen received the Meritorious Service Award from the Test Technology Technical Council of IEEE Computer Society “for significant services as Program Chair of the IEEE International Workshop on Testing Three-Dimensional Stacked ICs (3D-TEST) since 2010”.

Imec received the Research Institute of the Year 2017 award from 3DinCites (https://www.3dincites.com/3d-incites-awards/2017-3d-incipes-awards-winners/).

Erik Jan Marinissen received the Emerging Technology Award 2017 from the IEEE Standards Association “for his passion and initiative supporting the creation of a 3D Test Standard” (https://standards.ieee.org/about/awards/etech).

References

chips with several functions on them can be “disaggregated” or “disintegrated” into separate functions. These separated functions can be fabricated at different scaling nodes to optimize final performance and reintegrated onto a 2.5D silicon interposer. This strategy also allows for IP reuse of such known good chiplets in other designs.

The current DoD DARPA program, Common Heterogeneous Integration, and IP Reuse Strategies (CHIPS), is attempting to standardize communication interfaces and physical sizes to allow for proliferation of this technology into both the commercial and military worlds.

In fact, Intel, a leading member of the CHIPS program, recently indicated that starting in 2019 it will separate various processor components into smaller chiplets, each of which can be manufactured using an optimum (performance/cost) production node. Thus, Intel could deliver “10nm CPUs”, which could have 14nm and 22nm chiplet modules within them. So, memory, graphics, power regulation, and AI function could all constitute separate chiplets, some of which could be stacked with TSVs to a high-density silicon interposer.

What does the future hold?

With an end coming to CMOS scaling, something new will be taking its place. It is not clear what that new technology will be, but it is certain that it will take more than a decade to implement. The new technology will ultimately determine where packaging will go, but at this point we can only all guess what that will be. But, one thing we can say about chip packaging is, “we’ve come a long way baby!”

About the Author

Dr. Phil Garrou is a subject matter expert for DARPA and runs his consulting company Microelectronic Consultants of NC in the RTP NC area. He retired from Dow Chemical in 2004 as Global Director of Technology for their Advanced Electronic Materials business unit. Phil has served as Technical VP and President of both IEEE EPS and IMAPS and is a Fellow of both organizations. He has edited several microelectronic texts including McGraw Hill’s “Multichip Module Handbook” and Wiley VCH’s “Handbook of 3D Integration”. He has won the Milton Kiver Award for Excellence in Electronic Packaging (1994); the Fraunhofer International Adv. Packaging Award (2002); the IEEE CPMT Sustained Technical Achievement Award (2007), the IMAPS Ashman Award (2000) and most recently the American Chemical Society Award for Team Innovation (2017). His weekly publication Insights From the Leading Edge (IFITLE) has been a weekly advanced packaging blog since 2010.
