Abstract. We investigate the decidability of the problem of generalised soundness for Workflow nets: “Every marking reachable from an initial marking with k tokens on the initial place terminates properly, i.e. it can reach a marking with k tokens on the final place, for an arbitrary natural number k ”. We start with considering simple correctness criteria for Workflow nets and reduce them to the check of structural properties formulated in terms of traps and siphons, which can be easily checked. We call the nets that possess those properties Batch Workflow nets (BWF-nets). We show that every WF-net is either not sound or it can be transformed to a BWF-net with the same behaviour. Then we use algebraic methods to prove that generalized soundness is decidable for BWF-nets and give a decision procedure.

Keywords: Petri nets; workflows; verification; soundness, decidability.

1 Introduction

Petri nets are widely used for the modelling and verification of workflows. In [1], the class of Workflow (Petri) nets (WF-nets) was defined. A Petri net is a WF-net iff it satisfies certain structural properties, namely it possesses one source place (initial place) and one sink place (final place) and all other nodes lie on paths from the source to the sink place. The main correctness criterion introduced there was *soundness*. The requirements a sound workflow net should meet are (1) the reachability of a marking with a single token on the final place from any marking reachable from the marking with one token on the initial place, (2) the uniqueness of the marking containing a token on the final place, and (3) the absence of dead transitions for the net with a single token on the initial place. Soundness for WF-nets is decidable, and the decision procedure has been implemented e.g. in the WOFLAN tool [8].

In [4] we showed that the notion of soundness from [1] is *not compositional*, and moreover, it does not allow for handling of multiple cases in the WF-net. We introduced there a generalized soundness notion that amounts to *proper termination* of all markings obtained from markings with multiple tokens on the initial place, which corresponds to the processing of batches of cases in the WF-net. With proper termination for marking m obtained from a marking with k tokens on the initial place, we mean that there exists a firing sequence leading from m to the marking with k tokens on the final place. We proved that generalised soundness is *compositional*. The original soundness notion from [1] corresponds to 1-soundness in our case. Deciding generalised soundness is harder than deciding 1-soundness, since the straightforward approach involves an infinite number of checks of

proper termination. We did not solve the problem of soundness in [4] but defined a class of nets (ST-nets) that are sound by construction. In this paper we prove that the problem of (generalised) soundness is *decidable* for arbitrary WF-nets and describe a decision procedure for it.

We start with considering simple *behavioural* correctness criteria for WF-nets: *non-redundancy* and *non-persistency*. Non-redundancy means that every place can be marked and every transition can fire, provided that the initial place contains enough tokens, while non-persistency means that all places (except for the final one) can become empty again, lest some garbage would be left after the processing of the case is finished. We show that the WF-nets meet non-redundancy and non-persistency requirements iff they satisfy a simple *structural* characterisation: all proper siphons of these nets contain the initial place and all proper traps contain the final place. We call this class of WF-nets *Batch Workflow nets (BWF-nets)*. We show that every WF-net is either not sound (in case it contains persistent places) or it can be transformed to a BWF-net with the same behaviour (by removing redundant places and transitions).

In the second half of the paper we consider the problem of (generalised) soundness for BWF-nets and prove that this problem is *decidable*. The decidability proof is based on two ideas. First, we extend the set \mathcal{R} of markings reachable from the initial markings upto a set \mathcal{G} that has a ‘regular’ algebraic structure and show that the notion of soundness can be equally defined by requiring proper termination of all markings of this extended set \mathcal{G} . And second, we use the regularity of the structure of this set to show that it is enough to check proper termination for the markings of a finite subset Γ of \mathcal{G} to prove the proper termination of all markings from \mathcal{G} . Thus, the infinite set of markings in the initial formulation of the problem of generalised soundness can be reduced to a finite set due to the clean algebraic model of Petri nets.

The rest of the paper is organised as follows. In Section 2, we sketch the basic definitions related to Petri nets and Workflow nets. In Section 3 we introduce the notion of Batch Workflow Nets. In Section 4 we prove that the problem of generalised soundness is decidable. In Section 5 we illustrate the decision procedure for soundness on a concrete example. We conclude in Section 6 with discussion of the obtained results and directions for future work.

2 Preliminaries

\mathbb{N} denotes the set of natural numbers, \mathbb{Z} the set of integers and \mathbb{Q} the set of rational numbers. \mathbb{Q}^+ stands for the set of non-negative rational numbers.

Let P be a set. A *bag (multiset)* m over P is a mapping $m : P \rightarrow \mathbb{N}$. The set of all bags over P is \mathbb{N}^P . We use $+$ and $-$ for the sum and the difference of two bags and $=, <, >, \leq, \geq$ for comparisons of bags, which are defined in a standard way. We overload the set notation, writing \emptyset for the empty bag and \in for the element inclusion. We write $m = 2[p] + [q]$ for a bag m with $m(p) = 2$, $m(q) = 1$, and $m(x) = 0$ for all $x \notin \{p, q\}$. For a sum over the

elements of a bag m we write $\sum_{p \in m} f(p)$ (assuming that every p appears in the sum $m(p)$ times) rather than $\sum_{p \in m} m(p) \cdot f(p)$.

For (finite) *sequences* of elements over a set T we use the following notation: The empty sequence is denoted with ϵ ; a non-empty sequence can be given by listing its elements between angle brackets. The *Parikh vector* $\vec{\sigma} : T \rightarrow \mathbb{N}$ of a sequence σ maps every element $t \in T$ to the number of occurrences of t in σ .

Transition Systems A *transition system* is a tuple $E = \langle S, Act, T \rangle$ where S is a set of *states*, Act is a finite set of *action names* and $T \subseteq S \times Act \times S$ is a *transition relation*. A *process* is a pair $\langle E, s_0 \rangle$ where E is a transition system and $s_0 \in S$ an initial state. We denote (s_1, a, s_2) from T as $s_1 \xrightarrow{a} s_2$, and we say that a leads from s_1 to s_2 . For a sequence of transitions $\sigma = \langle t_1, \dots, t_n \rangle$ we write $s_1 \xrightarrow{\sigma} s_2$ when $s_1 = s^0 \xrightarrow{t_1} s^1 \xrightarrow{t_2} \dots \xrightarrow{t_n} s^n = s_2$, and $s_1 \xrightarrow{\sigma}$ when $s_1 \xrightarrow{\sigma} s_2$ for some s_2 . In this case we say that σ is a trace of E . Finally, $s_1 \xrightarrow{*} s_2$ means that there exists a sequence of transitions $\sigma \in T^*$ such that $s_1 \xrightarrow{\sigma} s_2$.

Petri nets A *Petri net* is a tuple $N = \langle P, T, F^+, F^- \rangle$, where:

- P and T are two disjoint non-empty finite sets of *places* and *transitions* respectively, the set $P \cup T$ are the *nodes* of N ;
- F^+ and F^- are mappings $(P \times T) \rightarrow \mathbb{N}$ that are *flow functions* from transitions to places and from places to transitions respectively.

$F = F^+ - F^-$ is the *incidence matrix* of net N .

We present nets with the usual graphical notation.

Markings are states (configurations) of a net. Depending on the context, we interpret a *marking* m of N either as a bag over P (in Section 3) or as a vector from $P \rightarrow \mathbb{N}$ (in Sections 4 and 5)). We denote the set of all markings reachable in net N from marking m as $\mathcal{R}(m)$. The set of markings from which marking m is reachable is denoted as $\mathcal{S}(m)$.

Given a transition $t \in T$, the *preset* $\bullet t$ and the *postset* $t \bullet$ of t are the *bags* of places where every $p \in P$ occurs in $\bullet t$ $F^-(p, t)$ times and in $t \bullet$ $F^+(p, t)$ times. Analogously we write $\bullet p, p \bullet$ for pre- and postsets of places. We overload this notation further and apply preset and postset operations to a set B of places: $\bullet B = \{t \mid \exists p \in B : t \in \bullet p\}$ and $B \bullet = \{t \mid \exists p \in B : t \in p \bullet\}$. Note that $\bullet B$ and $B \bullet$ are not bags but sets. We will say that node n is a *source* node iff $\bullet n = \emptyset$ and n is a *sink* node iff $n \bullet = \emptyset$. A *path* of a net is a sequence $\langle x_0, \dots, x_n \rangle$ of nodes such that $\forall i : 1 \leq i \leq n : x_{i-1} \in \bullet x_i$.

A transition $t \in T$ is *enabled* in marking m iff $\bullet t \leq m$. An enabled transition t may fire. This results in a new marking m' defined by $m' \stackrel{\text{def}}{=} m - \bullet t + t \bullet$. We interpret a Petri net N as a transition system/process where markings play the role of states, firings of the enabled transitions define the transition relation and the initial marking corresponds to the initial state. The notion of reachability for Petri nets is inherited from the transition systems. For a firing sequence σ in a net N , we define $\bullet \sigma$ and $\sigma \bullet$ respectively as $\sum_{t \in \sigma} \bullet t$ and $\sum_{t \in \sigma} t \bullet$, which are the sums of all tokens consumed/produced during the firings of σ . So $m \xrightarrow{\sigma} (m + \sigma \bullet - \bullet \sigma)$. We will use the well-known *Marking Equation Lemma*:

Lemma 1 (Marking Equation). *Given a finite firing sequence σ of a net $N: m \xrightarrow{\sigma} m'$, the following equation holds: $m' = m + F^+ \cdot \vec{\sigma} - F^- \cdot \vec{\sigma}$, or in other words, $m' = m + F \cdot \vec{\sigma}$.*

Note that the reverse is not true: not every marking m' that is representable as a sum $m + F \cdot v$ for some $v \in \mathbb{N}^T$ is reachable from the marking m .

Traps and Siphons (see [2]) A set R of places is a *trap* if $R^\bullet \subseteq \bullet R$. The trap is a *proper trap* iff it is not empty. A set R of places is a *siphon* if $\bullet R \subseteq R^\bullet$. The siphon is a *proper siphon* iff it is not empty. Important properties of traps and siphons are that *marked traps remain marked* and *unmarked siphons remain unmarked* whatever transition firings would happen. As follows from the definition, traps and siphons are dual by their nature.

Place Invariants (see [5]) A *place invariant* is a row vector $I : P \rightarrow \mathbb{Q}$ such that $I \cdot F = 0$. When talking about invariants, we consider markings as *vectors*. We will say that markings m_1 and m_2 *agree on a place invariant I* if $I \cdot m_1 = I \cdot m_2$ (see [3]).

Lemma 2. *Two markings m_1, m_2 agree on all place invariants iff the equation $m_1 + F \cdot x = m_2$ has some rational-valued solution for x .*

The main property of place invariants is thus that any two markings m_1, m_2 such that $m_1 \xrightarrow{*} m_2$ agree on all place invariants. The check whether the two markings m_1, m_2 agree on all place invariants can be done by a simple check whether $\mathcal{I} \cdot m_1 = \mathcal{I} \cdot m_2$, where \mathcal{I} is a matrix that consists of basis place invariants as rows.

Workflow Petri nets In this paper we primarily focus upon the *Workflow Petri nets* (*WF-nets*) [1]. As the name suggests, WF-nets are used to model the ordering of tasks in workflow processes. The initial and final nodes indicate respectively the initial and final states of processed cases.

Definition 3. *A Petri net N is a Workflow net (WF-net) iff:*

1. *N has two special places: i and f . The initial place i is a source place, i.e. $\bullet i = \emptyset$, and the final place f is a sink place, i.e. $f^\bullet = \emptyset$.*
2. *For any node $n \in (P \cup T)$ there exists a path from i to n and a path from n to f . (We call this property the path property of WF-nets.)*

In this paper, we study the processing of batches of tasks in Workflow nets, meaning that the initial place of a Workflow net may contain an arbitrary number of tokens. Our goal is to provide correctness criteria for the design of these nets. One natural correctness requirement is *proper termination*, which is called *soundness* in the WF-net theory. We will use the generalised notion of soundness for WF-nets introduced in [4]:

Definition 4. *We say that a WF-net N with marking $m \in \mathcal{R}(k[i])$ terminates properly iff $m \xrightarrow{*} k[f]$.*

N is k -sound for some $k \in \mathbb{N}$ iff for all $m \in \mathcal{R}(k[i])$, (N, m) terminates properly.

N is sound iff it is k -sound for all $k \in \mathbb{N}$.

Fig. 1. Redundant and persistent places

We will use terms *initial* and *final* markings for markings $k[i]$ and $k[f]$ respectively ($k \in \mathbb{N}$). We will write $\mathbf{0}$ for the vector representation of marking \emptyset , \mathbf{i} for the vector representation of marking $[i]$ and \mathbf{f} for the vector representation of marking $[f]$. For every marking m reachable from an initial marking $k[i]$ holds: $\mathcal{I} \cdot m = \mathcal{I} \cdot (k \cdot \mathbf{i})$, and if net N with marking m terminates properly, then $\mathcal{I} \cdot m = \mathcal{I} \cdot (k \cdot \mathbf{f})$.

3 Batch Workflow Nets

We are interested in the correct and optimal design of WF-nets. Ideally, correctness requirements should be formulated as requirements on the structure of the net (thus, they can be easily checked) and they should guarantee the correctness of the net behaviour. In this section, we consider behavioural criteria of the correct design and reduce them to structural ones.

3.1 Structural Non-Redundancy for Workflow Nets

Besides soundness, a logical requirement for the correct design of a WF-net is *non-redundancy*, namely: every transition of the net can potentially fire and every place of the net can potentially obtain tokens, provided that there are enough tokens in the initial place. WF-net N_1 in Fig. 1 does not satisfy this requirement because transition d can never fire and place s can never get tokens. So d and s are *redundant*. At the same time, it should be possible for every place (except for f) to become unmarked again—otherwise the net is guaranteed to be not sound, as e.g. net N_2 in Fig. 1—place s can obtain tokens but it can never become unmarked after that, i.e. this place is *persistent*. In formal terms:

Definition 5. Let $N = \langle P, T, F^+, F^- \rangle$ be a WF-net.

A place $p \in P$ is non-redundant iff there exist $k \in \mathbb{N}$ and $m \in \mathbb{N}^P$ such that $k[i] \xrightarrow{*} m \wedge p \in m$.

A place $p \in P$ is non-persistent iff there exist $k \in \mathbb{N}$ and $m \in \mathbb{N}^P$ such that $p \in m \wedge m \xrightarrow{*} k[f]$.

A transition t is non-redundant iff there exist $k \in \mathbb{N}$ and $m \in \mathbb{N}^P$ such that $k[i] \xrightarrow{*} m \xrightarrow{t}$.

The following lemma presents these desirable behavioural properties in more general terms:

Lemma 6. (1) A WF-net N has no redundant places iff every marking is majorated by a marking reachable from some initial marking $k[i]$, i.e.

$$\forall m \in \mathbb{N}^P \exists k \in \mathbb{N}, m' \in \mathcal{R}(k[i]) : m' \geq m.$$

(2) A WF-net N has no persistent places iff every marking is majorated by a marking from which some final marking $k[f]$ is reachable, i.e.

$$\forall m \in \mathbb{N}^P : \exists k \in \mathbb{N}, m' \in \mathcal{S}(k[f]) : m' \geq m.$$

Proof. (1) If every marking can be majorated by a marking reachable from some $k[i]$, then every marking $[p]$, $p \in P$ can be majorated and p is non-redundant. In the opposite direction: for every p there exist k_p, m_p , such that $k_p[i] \xrightarrow{*} m_p$ where $m_p \geq [p]$. Then we can majorate a given marking m by a marking $m' = \sum_{p \in m} m_p$ reachable from $(\sum_{p \in m} k_p)[i]$. (2) can be proved similarly. \square

As an immediate consequence we obtain the following property:

Lemma 7. A WF-net N has no redundant places iff it has no redundant transitions.

Proof. Let N has no redundant places. Consider an arbitrary transition $t \in T$. By applying property (1) of Lemma 6 to $\bullet t$ we obtain that t can get enabled, and hence it is non-redundant.

Now assume that N has no redundant transitions. Consider an arbitrary place $p \in P \setminus [i]$. Since N is a WF-net, $\bullet p \neq \emptyset$, and since all transitions are non-redundant, transitions from $\bullet p$ can fire and so p can get marked. Thus p is non-redundant. \square

Non-redundancy and non-persistency are behavioural properties. They imply though the following restrictions on the structure of the net: all proper siphons of the net should contain i and all proper traps should contain f . If N contained a proper siphon without i , the transitions consuming tokens from places of that siphon would be dead, no matter how many tokens are inserted into i . Similarly, if N contained a trap without f , the net could not terminate properly. It is not surprising that the absence of traps and siphons is a necessary condition for the correctness of the design. What is more interesting is that the absence of such siphons and traps is a *sufficient* condition for the absence of redundant and persistent places respectively: if a net has a redundant place, there exists a proper siphon without i , and if a net has a persistent place, there exists a proper trap without f , i.e. these behavioural and structural characteristics are equivalent for WF-nets:

Theorem 8. Let $N = \langle P, T, F^+, F^- \rangle$ be a WF-net. Then the following holds:

- (1) N has no redundant places iff $P \setminus \{i\}$ contains no proper siphon.
- (2) N has no persistent places iff $P \setminus \{f\}$ contains no proper trap.

Proof. (1) Let $X \subseteq P \setminus \{i\}$ be a proper siphon. Since an unmarked siphon stays unmarked, places from X are redundant.

In the opposite direction: Let $X \subseteq P \setminus \{i\}$ be the set of all redundant places of N . We will prove that X is a siphon. Consider some $t \notin X^\bullet$; $\bullet t$ contains no places from X and hence all places from $\bullet t$ are non-redundant. Then for every place p in $\bullet t$ there exists a

input : A Petri net $N = (P, T, F^+, F^-)$ and $S \subseteq P$;
output: $X \subseteq S$;

$X = S$;
while there exists $p \in X$ and $t \in \bullet p$ such that $t \notin X^\bullet$ do $X = X \setminus \{p\}$;
return(X);

Fig. 2. Algorithm for finding the maximal siphon in a set of places S

marking $m_p \geq [p]$ reachable from some $k_p[i]$, $k_p \in \mathbb{N}$. Taking a sum of corresponding initial markings we obtain an initial marking from which a marking $m \geq \bullet t$ can be reached. Thus t can fire and all places from t^\bullet can obtain tokens, i.e. they are non-redundant. Therefore, $t^\bullet \cap X = \emptyset$ and so $t \notin \bullet X$. Hence $(T \setminus X^\bullet) \subseteq (T \setminus \bullet X)$, and so X is a siphon. Thus every WF-net with redundant places contains a proper siphon in $P \setminus \{i\}$.

(2) can be proved analogously. □

To check that $P \setminus \{i\}$ contains no proper siphon it is enough to compute the largest siphon X in $P \setminus \{i\}$ in a standard manner [7] (see Fig.2): initialize X with $P \setminus \{i\}$ and remove places that belong to t^\bullet for some t such that $t \notin X^\bullet$ until the fixed point is reached. The largest trap not containing f can be computed with a similar algorithm.

As a spin-off of the check for absence of traps and siphons, we get a check of the path property of a WF-net:

Lemma 9. *Let $N = \langle P, T, F^+, F^- \rangle$ be a Petri net with a single source place i and a single sink place f , and every transition of N has at least one input and one output place. Moreover, $P \setminus \{i\}$ contains no proper siphon and $P \setminus \{f\}$ contains no trap. Then N is a WF-net.*

Proof. Consider an arbitrary node n and the set X of all places such that for every place $p \in X$ there is a path from p to n . We will show that X is a proper siphon, which implies that $i \in X$ and so there exists a path from i to n .

The set X is nonempty: If n is a place then $n \in X$ (since there is a path from n to n), and if n is a transition then its input places are in X . X is a proper siphon: For every transition t , if $t \in \bullet X$ then there is a path from t to n , and hence there is a path from places from $\bullet t$ to n and so every input place of t is in X . Since $\bullet t \neq \emptyset$, we have $t \in X^\bullet$. Thus, X is a proper siphon indeed.

Similarly, the set of places to which there is a path from n is a trap, and so there is a path from n to f . Thus N is indeed a WF-net. □

Thus we obtained a characterization that guarantees non-redundancy and non-persistency for WF-nets, and moreover it serves as a check of the path property.

3.2 Batch Workflow nets

Since we are interested in the class of WF-nets that have no redundant or persistent places, we introduce the notion of *Batch Workflow nets* by imposing requirements on the structure of the net:

Definition 10. *A Batch Workflow net (BWF-net) N is a Petri net that has the following properties:*

- (1) N has a single source place i and a single sink place f ;
- (2) every transition of N has at least one input and one output place;
- (3) every siphon of N contains i ;
- (4) every trap of N contains f .

The purpose of imposing structural requirements in the BWF-net definition resembles the purpose of one of the requirements on sound WF-nets from [1]. Sound WF-nets are defined there as nets where

- (1) $\forall m \in \mathcal{R}([i]) : m \xrightarrow{*} [f]$,
- (2) $\forall m \in \mathcal{R}([i]) : m \geq [f] \Rightarrow m = [f]$,
- (3) $\forall t \in T : \exists m, m' : [i] \xrightarrow{*} m \xrightarrow{t} m'$.

Our definition of soundness is stronger than requirement (1) from the above definition: it corresponds to 1-soundness in our definition. We do not use requirement (2) since it follows immediately from (1) (we prove the implication in a generalized form that is applicable to nets with multiple tokens on i):

Lemma 11. *Let N be a WF-net such that $\forall m \in \mathcal{R}(k[i]) : m \xrightarrow{*} k[f]$. Then $\forall m \in \mathcal{R}(k[i]) : m \geq k[f] \Rightarrow m = k[f]$.*

Proof. Consider a marking $m \in \mathcal{R}(k[i])$ such that $m \geq k[f]$, i.e. $m = m' + k[f]$ for some $m' \geq \emptyset$. Since $m \in \mathcal{R}(k[i])$, $m \xrightarrow{*} k[f]$, i.e. $m' + k[f] \xrightarrow{*} k[f]$. Since $f^\bullet = \emptyset$, we have $m' \xrightarrow{*} \emptyset$. However, every transition of a WF-net has at least one output place. Thus $m' = \emptyset$ and so $m = k[f]$. \square

We do not include requirement (3) in the definition of soundness. In fact we do not require all the transitions to be live in $(N, [i])$, since we allow batches of tasks to be processed in the net. The definition of BWF-nets implies that the net has no redundant transitions, which corresponds to (3).

In the rest of the paper we focus on the problem of soundness for BWF-nets. Working with BWF-nets instead of WF-nets does not limit the applicability of our approach: Let a WF-net N be given. First, we find a maximal siphon X in $P \setminus \{i\}$. All places from X are redundant (see Theorem 8). Thus, transitions from X^\bullet never get enabled and are redundant as well. Hence, by removing places from X and transitions from X^\bullet together with the corresponding ingoing and outgoing arcs we obtain a net N_1 with the same behavior as the one of net N , whatever initial marking $k[i]$ is chosen for these nets. N_1 is either not a WF-net any more (the path condition gets violated, or the place f is removed) and so we can make the conclusion that N was ill-designed, or N_1 is a WF-net with the same

behavior as the original net N but without redundant places. So N_1 is an improved version of N . Further, we check whether net N_1 has persistent places. If yes, we may conclude that N_1 is not a sound WF-net. Otherwise, N_1 is a BWF-net.

4 Soundness is decidable

In this section, we show that the problem of soundness is decidable for BWF-nets. As indicated before, this implies decidability of (general) soundness for WF-nets. We first discuss the necessary theoretical issues and then move to the actual decision procedure.

4.1 Decidability of Soundness

Proper termination for a given marking can be easily checked by using standard reachability algorithms. Deciding soundness is more intricate: A straightforward approach would require an *infinite* number of checks of proper termination (by checking proper termination for every marking reachable from some *arbitrary initial marking*). We shall try and reduce the check of soundness to the check of proper termination for a *finite* set of markings.

Consider the set of all markings reachable from some initial marking in a BWF-net N : $\mathcal{R} = \bigcup_{k \in \mathbb{N}} \mathcal{R}(k \cdot \mathbf{i})$. Every $\mathcal{R}(k \cdot \mathbf{i})$ is a subset of the set

$$\mathcal{G}_k = \{k \cdot \mathbf{i} + F \cdot v \mid v \in \mathbb{Z}^T\} \cap \mathbb{N}^P$$

(see Lemma 1). Note that $\mathcal{R}(k \cdot \mathbf{i}) \subseteq \mathcal{G}_k$ but in general $\mathcal{G}_k \not\subseteq \mathcal{R}(k \cdot \mathbf{i})$. For every marking m from \mathcal{G} holds $\mathcal{I} \cdot m = \mathcal{I} \cdot (k \cdot \mathbf{i})$ (\mathcal{I} is a matrix with basis invariants as rows). Clearly, if a BWF-net is sound, then $\mathbf{i} \xrightarrow{*} \mathbf{f}$, and hence $\mathcal{I} \cdot \mathbf{i} = \mathcal{I} \cdot \mathbf{f}$ (see Lemma 1 and Lemma 2). This is the *first soundness check* we perform. Further on, we will assume that $\mathcal{I} \cdot \mathbf{i} = \mathcal{I} \cdot \mathbf{f}$ holds for the net under consideration.

We now formulate the lemma that is fundamental for deciding soundness (in the proof we use the fact that N is a *BWF-net*, and so it has no redundant places).

Lemma 12. *Let N be a sound BWF-net and let $m \in \mathcal{G}_k$ for some $k \in \mathbb{N}$. Then there exists $\ell \in \mathbb{N}$ such that $(k + \ell) \cdot \mathbf{i} \xrightarrow{*} m + \ell \cdot \mathbf{f}$.*

Proof. Let m be a marking from \mathcal{G}_k , i.e. $m = k \cdot \mathbf{i} + F \cdot v$ for some $v \in \mathbb{Z}^T$. Then there exist $v_1, v_2 \in \mathbb{N}^T$ such that $v = v_1 - v_2$. Note that $F = F^+ - F^-$. So

$$m = k \cdot \mathbf{i} + F^+ \cdot v_1 + F^- \cdot v_2 - F^- \cdot v_1 - F^+ \cdot v_2.$$

By Lemma 6, we can majorate markings $F^+ \cdot v_1, F^- \cdot v_2$: There exist $a, b \in \mathbb{N}$ and markings A, B such that $a \cdot \mathbf{i} \xrightarrow{*} A + F^+ \cdot v_1$ and $b \cdot \mathbf{i} \xrightarrow{*} B + F^- \cdot v_2$. Then $(k + a + b) \cdot \mathbf{i} \xrightarrow{*} k \cdot \mathbf{i} + A + F^+ \cdot v_1 + B + F^- \cdot v_2 = m + A + F^- \cdot v_1 + B + F^+ \cdot v_2$.

Let γ_2 be an arbitrary firing sequence with $\vec{\gamma}_2 = v_2$. Then $b \cdot \mathbf{i} \xrightarrow{*} B + F^- \cdot v_2 \xrightarrow{\gamma_2} B + F^+ \cdot v_2$, and since N is sound, $B + F^+ \cdot v_2 \xrightarrow{*} b \cdot \mathbf{f}$. Now consider a marking $A + F^- \cdot v_1$. For an

arbitrary firing sequence γ_1 with $\vec{\gamma}_1 = v_1$, $A + F^- \cdot v_1 \xrightarrow{\gamma_1} A + F^+ \cdot v_1$. Moreover, we have $a \cdot \mathbf{i} \xrightarrow{*} A + F^+ \cdot v_1$, and since N is sound, $A + F^- \cdot v_1 \xrightarrow{*} A + F^+ \cdot v_1 \xrightarrow{*} a \cdot \mathbf{f}$. Thus we obtain $m + A + F^- \cdot v_1 + B + F^+ \cdot v_2 \xrightarrow{*} m + (a + b) \cdot \mathbf{f}$. So with $\ell = a + b$ the lemma holds. \square

This immediately leads us to the conclusion that every marking from \mathcal{G}_k should enable some firing sequence leading to $k \cdot \mathbf{f}$, lest the soundness condition gets violated.

Lemma 13. *Let N be a sound BWF-net and $m \in \mathcal{G}_k$. Then $m \xrightarrow{*} k \cdot \mathbf{f}$.*

Proof. By Lemma 12, there exists $\ell \in \mathbb{N}$ such that $(k + \ell) \cdot \mathbf{i} \xrightarrow{*} m + \ell \cdot \mathbf{f}$. Since N is sound, $m + \ell \cdot \mathbf{f} \xrightarrow{*} (k + \ell) \cdot \mathbf{f}$. Since f is a sink place, we deduce $m \xrightarrow{*} k \cdot \mathbf{f}$. \square

One more conclusion we can draw now is the following:

Corollary 14. *Let N be a sound BWF-net. Then $\mathcal{I} \cdot x = \mathbf{0}$ for $x \in (\mathbb{Q}^+)^P$ iff $x = \mathbf{0}$.¹*

Proof. Let $\mathcal{I} \cdot x = \mathbf{0}$ for some $x > \mathbf{0}$. Then we can find $\ell \in \mathbb{N}$ such that $y = \ell \cdot x$ is in \mathbb{N}^P . Note that $\mathcal{I} \cdot y = \mathbf{0}$ as well. So y agrees with marking $\mathbf{0}$ on all place invariants. By Lemma 2, $y = F \cdot v$ for some $v \in \mathbb{Q}^T$. Then there exists $n > 0$ such that $w = n \cdot v \in \mathbb{Z}^T$ and thus $z = n \cdot y = F \cdot w$ is also the solution for the equation $\mathcal{I} \cdot x = \mathbf{0}$. Note that z is a non-empty marking from \mathcal{G}_0 . By Lemma 13, we have $z \xrightarrow{*} \mathbf{0}$. This is in contradiction with the fact that for any transition of N , $t^\bullet \neq \emptyset$. \square

Thus, the *second soundness check* we perform is the check whether the equation $\mathcal{I} \cdot x = \mathbf{0}$ has only the trivial solution on \mathbb{N}^P . If so, we can conclude that \mathcal{G}_k 's are *disjoint* sets:

Corollary 15. *Let N be a BWF-net such that the equation $\mathcal{I} \cdot x = \mathbf{0}$ has only the trivial solution in \mathbb{N}^P . Then $\mathcal{G}_k \cap \mathcal{G}_\ell \neq \{\mathbf{0}\}$ implies $k = \ell$.*

Proof. Since $m \in \mathcal{G}_k$ implies $\mathcal{I} \cdot m = \mathcal{I} \cdot (k \cdot \mathbf{i})$ and $m \in \mathcal{G}_\ell$ implies $\mathcal{I} \cdot m = \mathcal{I} \cdot (\ell \cdot \mathbf{i})$, $m \in (\mathcal{G}_k \cap \mathcal{G}_\ell)$ implies $\mathcal{I} \cdot (k \cdot \mathbf{i}) = \mathcal{I} \cdot (\ell \cdot \mathbf{i})$. By Corollary 14, $k = \ell$. \square

Further on, we assume that $\mathcal{I} \cdot x = \mathbf{0}$ has only the trivial solution on \mathbb{N}^P and thus \mathcal{G}_k 's are disjoint sets. We define the *i-weight function* $w(m)$ of a marking m as a natural number k such that $\mathcal{I} \cdot m = \mathcal{I} \cdot (k \cdot \mathbf{i})$ ($w(m)$ is undefined if such a value k does not exist). All markings in \mathcal{G}_k have *i-weight* k .

Now we introduce the set $\mathcal{G} = \bigcup_{k \in \mathbb{N}} \mathcal{G}_k$, i.e.

$$\mathcal{G} = \{k \cdot \mathbf{i} + F \cdot v \mid k \in \mathbb{N} \wedge v \in \mathbb{Z}^T\} \cap \mathbb{N}^P,$$

and extend the notion of proper termination for all markings from \mathcal{G} : We say that a marking $m \in \mathcal{G}$ *terminates properly* iff $m \xrightarrow{*} w(m) \cdot \mathbf{f}$.

Lemma 16. *Let $m_1, m_2 \in \mathcal{G}$ be markings that terminate properly and $m = \lambda_1 m_1 + \lambda_2 m_2$ for some $\lambda_1, \lambda_2 \in \mathbb{N}$. Then $m \in \mathcal{G}$ and it terminates properly.*

¹ We overload the notation and use $\mathbf{0}$ for a zero-vector of an arbitrary dimension.

Proof. By the definition of \mathcal{G}_k , $(\lambda_1 m_1 + \lambda_2 m_2) \in \mathcal{G}_{\lambda_1 k_1 + \lambda_2 k_2}$ and $\mathcal{I} \cdot (\lambda_1 m_1 + \lambda_2 m_2) = \mathcal{I} \cdot ((\lambda_1 k_1 + \lambda_2 k_2) \cdot \mathbf{i})$. Thus $w(\lambda_1 m_1 + \lambda_2 m_2) = \lambda_1 w(m_1) + \lambda_2 w(m_2)$. Since $m_1 \xrightarrow{*} w(m_1) \cdot \mathbf{f}$ and $m_2 \xrightarrow{*} w(m_2) \cdot \mathbf{f}$, we have $\lambda_1 m_1 + \lambda_2 m_2 \xrightarrow{*} (\lambda_1 w(m_1) + \lambda_2 w(m_2)) \cdot \mathbf{f}$. \square

We now formulate a necessary and sufficient condition for soundness.

Theorem 17. *Let N be a BWF-net. Then N is sound iff all markings in \mathcal{G} terminate properly.*

Proof. (\Rightarrow): Suppose N is sound. Consider arbitrary $k \in \mathbb{N}, m \in \mathcal{G}_k$. By Lemma 13, $m \xrightarrow{*} k \cdot \mathbf{f}$.

(\Leftarrow): Suppose $\forall k \in \mathbb{N}, m \in \mathcal{G}_k : m \xrightarrow{*} k \cdot \mathbf{f}$. Let $k \cdot \mathbf{i} \xrightarrow{*} m$ for some k, m . Then $m \in \mathcal{G}_k$ and therefore $m \xrightarrow{*} k \cdot \mathbf{f}$. Hence N is sound. \square

We thus obtained a characterization of soundness involving the set \mathcal{G} rather than reachable markings. We shall use the regularity of the structure of \mathcal{G} to reduce the problem of proper termination of markings of \mathcal{G} to the problem of proper termination of some *finite subset* Γ of \mathcal{G} .

In order to construct Γ , we extend the set \mathcal{G} even further by making a step from integers to rational numbers and considering the set

$$\mathcal{H} = \{a \cdot \mathbf{i} + F \cdot v \mid a \in \mathbb{Q}^+ \wedge v \in \mathbb{Q}^T\} \cap (\mathbb{Q}^+)^P.$$

(We refer to the appendix for the definitions of algebraic notions that we use in the rest of this section.)

Lemma 18. *The set \mathcal{H} is a convex polyhedral cone. Moreover, there exists a finite set e_1, \dots, e_n of generators such that $e_1, \dots, e_n \in \mathcal{G}$.*

Proof. \mathcal{H} is a convex polyhedral cone. By Theorem 26, we can find generators E_1, \dots, E_n of \mathcal{H} . Each E_i is a linear combination of \mathbf{i} and the column vectors of F with *rational* coefficients. The lcm of the denominators divided by the gcd of the numerators gives for a given E_i the smallest rational number γ_i such that $\gamma_i E_i$ can be written as $k_i \cdot \mathbf{i} + F \cdot v_i$ with $k_i \in \mathbb{N}, v_i \in \mathbb{Z}^T$. Set $e_i = \gamma_i E_i$ for $i = 1, \dots, n$. Then the e_1, \dots, e_n are generators of \mathcal{H} and $e_1, \dots, e_n \in \mathcal{G}$. \square

We define our *finite* set Γ as

$$\Gamma = \left\{ \sum_i \alpha_i \cdot e_i \mid 0 \leq \alpha_i \leq 1 \right\} \cap \mathcal{G}$$

and show that the proper termination of any marking from \mathcal{G} can be reduced to the proper termination of markings from Γ . Note that e_1, \dots, e_n are in Γ .

Theorem 19. *Let N be a BWF-net such that $\mathcal{I} \cdot \mathbf{i} = \mathcal{I} \cdot \mathbf{f}$ and $\mathcal{I} \cdot x = \mathbf{0}$ has only the trivial solution in $(\mathbb{Q}^+)^P$. Further, let $\mathcal{G} = \{k \cdot \mathbf{i} + F \cdot v \mid k \in \mathbb{N} \wedge v \in \mathbb{Z}^T\} \cap \mathbb{N}^P$, $\mathcal{H} = \{a \cdot \mathbf{i} + F \cdot v \mid a \in \mathbb{Q}^+ \wedge v \in \mathbb{Q}^T\} \cap (\mathbb{Q}^+)^P$, $e_1, \dots, e_n \in \mathcal{G}$ be the generators of the cone \mathcal{H} and $\Gamma = \left\{ \sum_i \alpha_i \cdot e_i \mid 0 \leq \alpha_i \leq 1 \right\} \cap \mathcal{G}$. Then N is sound iff all markings from Γ terminate properly.*

Proof. (\Rightarrow): Let N be a sound WF-net. By Theorem 17 all markings of \mathcal{G} terminate properly. Since $\Gamma \subseteq \mathcal{G}$, all markings of Γ terminate properly.

(\Leftarrow): Let all markings from Γ terminate properly. Consider an arbitrary marking $m \in \mathcal{G}$. Since $m \in \mathcal{G}$, $m = n \cdot \mathbf{i} + F \cdot w$ for some $n \in \mathbb{N}, w \in \mathbb{Z}^T$. Since $\mathcal{G} \subseteq \mathcal{H}$ and so $m \in \mathcal{H}$, $m = \sum_i \lambda_i \cdot e_i$ with the $\lambda_i \in \mathbb{Q}^+$. We can represent m as $\sum_i \ell_i \cdot e_i + \sum_i \mu_i \cdot e_i$ where $\ell_i = \lfloor \lambda_i \rfloor$ (the integer part of λ_i) and $\mu_i = \lambda_i - \lfloor \lambda_i \rfloor$ (the fractional part of λ_i), i.e. $0 \leq \mu_i < 1$. We will prove that $m' = m - \sum_i \ell_i \cdot e_i = \sum_i \mu_i \cdot e_i$ is a marking from \mathcal{G} . First note that $m \in \mathbb{N}^P, e_i \in \mathbb{N}^P, \ell_i \in \mathbb{N}$ for all i . Thus $m' \in \mathbb{Z}^P$. Moreover, $\mu_i \geq 0$, which implies that $m' \geq \mathbf{0}$. Thus $m' \in \mathbb{N}^P$. Since $e_i \in \mathcal{G}$, they can be represented as $k_i \cdot \mathbf{i} + F \cdot v_i$ where $k_i \in \mathbb{N}, v_i \in \mathbb{Z}^T$. Since $m' = m - \sum_i \ell_i \cdot e_i$, we have $m' = k \cdot \mathbf{i} + F \cdot v$ with $k = n - \sum_i \ell_i \cdot k_i$ and $v = w - \sum_i \ell_i \cdot v_i$. Therefore, we can conclude that $k \in \mathbb{Z}$ and $v \in \mathbb{Z}^T$. Now we only have to show that $k \in \mathbb{N}$.

Note that since columns of F are not necessarily linearly independent, the representation of m' as $k \cdot \mathbf{i} + F \cdot v$ is not necessarily unique. However, k has the same value in every such a representation: Let $a = \mathcal{I} \cdot m'$ and $k \cdot \mathbf{i} + F \cdot v$ is some representation of m' . Then $\mathcal{I} \cdot m' = \mathcal{I} \cdot (k \cdot \mathbf{i}) + \mathcal{I} \cdot (F \cdot v)$. By the definition of place invariants, $\mathcal{I} \cdot (F \cdot v) = \mathbf{0}$. Thus $a = \mathcal{I} \cdot (k \cdot \mathbf{i})$. Due to Corollary 14, k is uniquely defined. Since $k = \sum_i \mu_i \cdot k_i$, $k \geq 0$ and so $k \in \mathbb{N}$. Therefore $m' \in \mathcal{G}$. Since $0 \leq \mu_i < 1$, $m' \in \Gamma$.

Since e_1, \dots, e_n and m' are markings from Γ and thus terminate properly, m terminates properly as well (Lemma 16). Thus, all markings in \mathcal{G} terminate properly and, due to Theorem 17, N is sound. \square

Thus we have reduced the problem of soundness to the problem of proper termination of a finite number of markings and hereby proved its decidability.

4.2 Decision Procedure

In this subsection, we describe the decision procedure for soundness in a systematic way. We do not claim algorithm status: we focused on clarity rather than efficiency here.

We start with trivial checks that can lead to the negative answer. First we find a set of basis place invariants and check that $\mathcal{I} \cdot \mathbf{i} = \mathcal{I} \cdot \mathbf{f}$. If not, the net is not sound. Then we check that the only solution of the equation $\mathcal{I} \cdot x = \mathbf{0}$ on $(\mathbb{Q}^+)^P$ is the trivial solution $x = \mathbf{0}$; otherwise the net is not sound (see Corollary 14). This second condition also guarantees the boundedness of the net:

Lemma 20. *Let N be a BWF-net such that the only solution of $\mathcal{I} \cdot x$ in $(\mathbb{Q}^+)^P$ is $x = \mathbf{0}$. Then $\mathcal{R}(k \cdot \mathbf{i})$ and $\mathcal{S}(k \cdot \mathbf{f})$ are finite sets for any $k \in \mathbb{N}$.*

Proof. Assume some $\mathcal{R}(k \cdot \mathbf{i})$ is an infinite set. Then there exist $m_1, m_2 \in \mathcal{R}(k \cdot \mathbf{i})$ such that $m_1 < m_2$ and $\mathcal{I} \cdot m_1 = \mathcal{I} \cdot m_2 = \mathcal{I} \cdot (k \cdot \mathbf{i})$. Then $\mathcal{I} \cdot (m_2 - m_1) = \mathbf{0}$ and thus $m_2 - m_1 = \mathbf{0}$. This is a contradiction with $m_1 < m_2$. Thus $\mathcal{R}(k \cdot \mathbf{i})$ is finite. Analogously, we prove that $\mathcal{S}(k \cdot \mathbf{f})$ is a finite set. \square

At the next step, we compute generators E_1, \dots, E_n of \mathcal{H} and rescale them to obtain generators $e_1, \dots, e_n \in \mathcal{G}$ of \mathcal{H} . Now our goal is to enumerate the markings of Γ .

The generators of the cone \mathcal{H} are not necessarily linearly independent (e.g. the set of generators can include vectors e, f, g and $f + g - e$). This implies that the representation of elements of the cone as nonnegative linear combinations of the cone generators are not necessarily unique. However, by Carathéodory's theorem (Theorem 27 in Appendix A), we can represent \mathcal{H} as $\mathcal{H} = \bigcup_j \mathcal{H}_j$, where \mathcal{H}_j 's are cones generated by vectors from some maximal subset $\mathcal{E}_j \subseteq \{e_1, \dots, e_n\}$ of *linearly independent vectors*. We define $\mathcal{G}_j \subseteq \mathcal{G}$ as $\mathcal{G}_j = (\mathcal{G} \cap \mathcal{H}_j)$ and $\Gamma_j \subseteq \Gamma$ as

$$\Gamma_j = \left\{ \sum_{e_i \in \mathcal{E}_j} \lambda_i e_i \mid 0 < \lambda_i \leq 1 \right\} \cap \mathcal{G}_j.$$

Note that $\mathcal{G} = \bigcup_j \mathcal{G}_j$ but in general $\Gamma \neq \bigcup_j \Gamma_j$ though $\Gamma \supseteq \bigcup_j \Gamma_j$. Still, the proper termination of markings from $\bigcup_j \Gamma_j$ guarantees the proper termination of markings in \mathcal{G} . We do not give a complete proof but sketch the main idea. Every $x \in \mathcal{G}$ is also an element of \mathcal{H} and so an element of some \mathcal{H}_j . Thus it can be represented as $\sum_{e_i \in \mathcal{E}_j} \lambda_i \cdot e_i$. Now we can use the same construction with the integer and the fractional part of λ_i as in the proof of Theorem 19 to prove that x is a nonnegative integer linear combination of markings that terminate properly, x terminates properly as well.

Now we will construct an algorithm for the enumeration of the elements of Γ_j . Since vectors in \mathcal{E}_j are linearly independent, any $x \in \mathcal{G}_j$ has a unique representation as a nonnegative linear combination of vectors from \mathcal{E}_j . Note that the dimension m of any set \mathcal{E}_i equals the dimension of the vector space $\{\lambda \cdot \mathbf{i} + F \cdot v \mid \lambda \in \mathbb{Q} \wedge v \in \mathbb{Q}^T\}$, thus all vectors from this vector space have unique representations as $\sum_{e_i \in \mathcal{E}_i} \lambda_i \cdot e_i$ where $\lambda_i \in \mathbb{Q}$. Now consider the set $\mathcal{U} \supseteq \mathcal{G}_j$ defined as $\mathcal{U} = \{k \cdot \mathbf{i} + F \cdot v \mid k \in \mathbb{N} \wedge v \in \mathbb{Z}^T\}$ (note that we do not require elements of \mathcal{U} to be nonnegative vectors). Every element of \mathcal{U} has a unique representation as a linear combination of vectors from \mathcal{E}_j . We define the translation functions $\theta_j : \mathcal{U} \rightarrow \Gamma_j$ as follows:

$$\theta_j \left(\sum_{e_i \in \mathcal{E}_j} \lambda_i \cdot e_i \right) = \sum_{e_i \in \mathcal{E}_j} \mu_i \cdot e_i \text{ where } \mu_i = \lambda_i - \lfloor \lambda_i \rfloor \text{ (the fractional part of } \lambda_i \text{)}.$$

We will use a simple property of the translation function:

Lemma 21. *For any markings $x, y \in \mathcal{H}_i$, $\theta_j(x + y) = \theta_j(x + \theta_j(y))$.*

Lemma 22. $\Gamma_j = \{\theta_j(x) \mid x \in \mathcal{U}\}$.

Proof. $\Gamma_j \subseteq \mathcal{G}_j \subseteq \mathcal{U}$ and for any $x \in \Gamma_j$, $\theta_j(x) = x$ (by the definition of θ), so $\Gamma_j \subseteq \{\theta_j(x) \mid x \in \mathcal{U}\}$.

For every $x \in \mathcal{G}_j$, $\theta_j(x) \in \Gamma_j$ (cf. the proof of Theorem 19).

For any $x \in (\mathcal{U} \setminus \mathcal{G}_j)$, there exist representations of x as $k \cdot \mathbf{i} + F \cdot v$ where $k \in \mathbb{N}, v \in \mathbb{Z}^T$ and as $\sum_i \lambda_i e_i$ with $e_i \in \mathcal{E}_i$ and $\lambda_i \in \mathbb{Q}$. We choose $y \in \mathcal{G}_j$, $y = \ell \cdot \mathbf{i} + F \cdot w = \sum_i \alpha_i e_i$ with $\ell \in \mathbb{N}, w \in \mathbb{Z}^T, \alpha \in \mathbb{N}, e_i \in \mathcal{E}_i$, such that $k + \ell \geq 0$ and $\alpha_i + \lambda_i \geq 0$ for all i . Now consider the marking $z = x + y$. By the choice of y , $z \geq \mathbf{0}$ and $z = (k + \ell) \cdot \mathbf{i} + F \cdot (v + w)$

input : a BWF-net N , a set of linearly independent vectors \mathcal{E}_i , translation function θ_j ;
output : the set X of markings;

$X = \{\mathbf{0}\}$;
repeat
 $X = X \cup \{\theta_j(x + \mathbf{i}) \mid x \in X\} \cup \{\theta_j(x \pm F_t) \mid x \in X \wedge t \in T\}$
until the fixed point is reached;
return(X);

Fig. 3. Algorithm for enumeration of Γ

with $(k + l) \in \mathbb{N}$ and $(v + w) \in \mathbb{Z}^T$, i.e. $z \in \mathcal{G}$. Moreover, $z = \sum_i (\alpha_i + \lambda_i) \cdot e_i$, i.e. it is a nonnegative linear combination of vectors from \mathcal{E}_i and thus $z \in \mathcal{G}_j$. Note that $\theta_j(y) = 0$, which means $\theta_j(z) = \theta_j(x)$. Since $z \in \mathcal{G}_j$, $\theta_j(z) \in \Gamma_j$ and so $\theta_j(x) \in \Gamma_j$. Thus $\Gamma_j \supseteq \{\theta_j(x) \mid x \in \mathcal{U}\}$. \square

Fig. 3 gives the algorithm that enumerates the elements of Γ_j . F_t stands there for the column of F that corresponds to transition t , i.e. that is a vector corresponding to $t^\bullet - \bullet t$.

Theorem 23. *The algorithm in Fig. 3 terminates and its output equals Γ_j .*

Proof. First we prove by induction on the iteration step number that $X \subseteq \Gamma_j$ at every iteration step. Let X_ℓ be the value of X at iteration ℓ . $X_0 = \{\mathbf{0}\}$ and by the definition of Γ_j , $\mathbf{0} \in \Gamma_j$. Now let $X_\ell \subseteq \Gamma_j$ at some step. Consider some $x \in X_\ell$ (and hence $x \in \Gamma_j$ and $x \in \mathcal{U}$). The elements added to X at iteration $(\ell + 1)$ are $(x + \mathbf{i})$ and $(x \pm F_t)$, $t \in T$. By the definition of \mathcal{U} , $(x + \mathbf{i}) \in \mathcal{U}$ and thus $\theta_j(x + \mathbf{i}) \in \Gamma_j$ by the definition of θ_j . Now consider a marking $(x \pm F_t)$, $t \in T$. By the definition of \mathcal{U} , $(x \pm F_t) \in \mathcal{U}$ and so $\theta_j(x \pm F_t) \in \Gamma_j$. Thus, $X \subseteq \Gamma_j$ at every iteration step. Since X grows monotonously and Γ_j is bounded, the algorithm terminates and it returns a subset X of Γ_j .

Now we will prove that $\Gamma_j \subseteq X$. Any marking $x \in \Gamma_j$ is a marking from \mathcal{U} and hence it can be represented as $m = k \cdot \mathbf{i} + F \cdot v$ for some $k \in \mathbb{N}$ and $v \in \mathbb{Z}^T$ with components $v_1, \dots, v_n \in \mathbb{Z}$. We define $\|x\| = k + \sum_j |v_j|$. Then for any x such that $\|x\| \leq l$, $\theta_j(x) \in X_l$. We prove it by induction on l . For $l = 0$ it holds trivially. Let it hold for some l . Consider $x = k \cdot \mathbf{i} + F \cdot v$ such that $\|x\| = l + 1$. If $k > 0$, $x = \mathbf{i} + ((k - 1) \cdot \mathbf{i} + F \cdot v)$. Note that for $y = (k - 1) \cdot \mathbf{i} + F \cdot v$, $\|y\| = l$ and thus $\theta_j(y) \in X_l$. By Lemma 21, $\theta_j(x) = \theta_j(\mathbf{i} + y) = \theta_j(\mathbf{i} + \theta_j(y))$. Since $\theta_j(y) \in X_l$, $\theta_j(\mathbf{i} + \theta_j(y))$ is in X_{l+1} by the definition of the algorithm, and thus $\theta_j(x) \in X_{l+1}$.

If $k = 0$ then $v \neq \mathbf{0}$, i.e. $v_j \neq 0$ for some j . We represent x as $F_{t_j} + (k \cdot \mathbf{i} + F \cdot v')$ where all components of v' equal the corresponding components of v , except for v'_j : $|v'_j| = |v_j| - 1$ and $v_j \cdot v'_j \geq 0$. Then we use a similar induction scheme to prove the statement.

Thus at iteration $l = \max_{x \in \Gamma_j} \|x\|$, X_l contains all elements of Γ_j . \square

When we found all markings of Γ_j 's, we check proper termination for every marking. To check whether a marking m terminates properly, it is enough to check whether $m \in \mathcal{S}(w(m) \cdot \mathbf{f})$. Since $\mathcal{S}(w(m) \cdot \mathbf{f})$ is a finite set (see Lemma 20), we can construct it by a

Fig. 4. Example net N

backward reachability analysis, starting with $X = \{w(m) \cdot \mathbf{f}\}$ and consequently augmenting this set by adding markings $\{x - F_t \mid x \in X \wedge t \in T \wedge (x - F_t) \geq \mathbf{0}\}$.

5 Example

We illustrate the decision procedure for soundness with an example. Consider net N depicted in Figure 4. (The net has weighted arcs as indicated.) We have $P = \{i, a, b, f\}$, $T = \{t, u, v, w\}$ and the incidence matrix

$$F = \begin{pmatrix} -1 & 0 & 0 & 0 \\ 3 & -2 & 8 & -1 \\ 1 & 2 & -8 & -3 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

First, we find the place invariants of the net. Solutions of the equation $I \cdot F = 0$ are vectors $I = k \cdot (4, 1, 1, 4)$, $k \in \mathbb{Q}$. Thus the matrix of basis invariants \mathcal{I} is $(4, 1, 1, 4)$. Now we check that $\mathcal{I} \cdot \mathbf{i} = \mathcal{I} \cdot \mathbf{f}$ indeed (the first and the last columns of \mathcal{I} coincide).

The cone \mathcal{H} for this example is the set $(\mathbb{Q}^+)^P$, i.e. \mathcal{H} is the cone generated by vectors $\mathbf{i}, \mathbf{a}, \mathbf{b}, \mathbf{f}$ corresponding to markings $[i], [a], [b], [f]$. These are vectors from \mathcal{H} , so they are representable as $a \cdot \mathbf{i} + F \cdot v$ for some $a \in \mathbb{Q}^+, v \in \mathbb{Q}^T$. By solving linear equations, we obtain the following representations of \mathbf{a} and \mathbf{b} .

$$\mathbf{a} = \frac{1}{4} \cdot \mathbf{i} + F \cdot \begin{pmatrix} 1/4 \\ 1/8 \\ 0 \\ 0 \end{pmatrix} \quad \text{and} \quad \mathbf{b} = \frac{1}{4} \cdot \mathbf{i} + F \cdot \begin{pmatrix} 1/4 \\ 5/8 \\ 0 \\ 0 \end{pmatrix}.$$

To find generators from \mathcal{G} we need to rescale these vectors. Thus, we obtain $e_1 = \mathbf{i}$, $e_2 = 8 \cdot \mathbf{a}$, $e_3 = 8 \cdot \mathbf{b}$, $e_4 = \mathbf{f}$. So we have defined our set Γ and we can find all the points inside it. In Figure 5, the points of Γ are depicted, projected on the (a, b) -plane. We have also depicted the transitions between them, from which it can be inferred that all grid points terminate. The net N is thus sound.

If the transition v were removed from N , the resulting net would not be sound, since the grid point e_3 no longer terminates. The net then is 1-sound but not 2-sound.

Fig. 5. Grid within Γ of net N

6 Conclusion

We have introduced a subclass of Workflow nets: *Batch Workflow nets (BWF-nets)* that have a simple structural characterisation based on traps and siphons. Batch Workflow nets are Workflow nets without redundant places and transitions and without persistent places. We have shown that Workflow nets with redundant places/transitions or with persistent places are ill-designed. Therefore, we moved from the study of Workflow nets to the study of Batch Workflow nets.

Since we are interested in the processing of batches of tasks in the net, we investigated the generalised notion of soundness introduced in [4] for Batch Workflow nets. We have proved that the generalised soundness is decidable and have described the decision procedure.

The decidability of soundness implies trivially the decidability of weak separability [4]. It remains still unclear whether strong separability is decidable.

Future work For the soundness decision procedure, we focused on the clarity rather than efficiency. It is still to be investigated how to solve the problem of soundness in an efficient manner and what complexity this algorithm would have. Besides, soundness preserving Petri net reduction techniques can be employed prior to the use of the soundness decision procedure to speed up the check.

Acknowledgements We want to thank our colleague Aart Blokhuis for useful discussions on algebraic issues.

A Appendix

Here we give the mathematical definitions and results we need (see e.g. [6] for more detail). Let E_n stand for an n -dimensional vector space over some number field (in our case the rational numbers). Let u be a vector. We write $u(x)$ for the value of the vector component corresponding to coordinate x .

A *convex combination* of the vectors u_1, u_2, \dots, u_n from E_n is a vector $u = \alpha_1 \cdot u_1 + \alpha_2 \cdot u_2 + \dots + \alpha_n \cdot u_n$ where the α_i are nonnegative scalars such that $\sum_i \alpha_i = 1$. A subset S of E_n is *convex* iff for all pairs of vectors u_1, u_2 any convex combination of them is also in S .

Lemma 24. *The intersection of two convex sets is convex.*

A set of vectors C is called a *cone* if, for every vector $u \in C$, $\lambda u \in C$ for every nonnegative λ . A convex cone C is *polyhedral* if $C = \{x \mid A \cdot x \leq \mathbf{0}\}$ for some matrix A , i.e. C is the intersection of finitely many linear half-spaces.

Lemma 25. *Let X, Y be convex polyhedral cones. Then $Z = X \cap Y$ is a convex polyhedral cone as well.*

Proof. Since X, Y are convex polyhedral cones, $X = \{x \mid A \cdot x \leq \mathbf{0}\}$ and $Y = \{y \mid B \cdot y \leq \mathbf{0}\}$ for some matrix A, B . Then $X \cap Y$ is defined as $\{z \mid C \cdot z \leq \mathbf{0}\}$ where C is the matrix composed of matrices A and B , namely a matrix whose rows are the ones of A and B . Thus $X \cap Y$ is a convex polyhedral cone. \square

A cone C is *finitely generated* if there exist vectors x_1, \dots, x_n such that $C = \{\sum_i \lambda_i \cdot x_i \mid \lambda_i \geq 0\}$. These vectors are called *generators* of C .

Theorem 26 (Farkas-Minkowski-Weyl). *A convex cone is polyhedral iff it is finitely generated.*

A set of generators of a convex polyhedral cone can be obtained by solving linear equations defining the cone.

Theorem 27 (Carathéodory's theorem). *Let C be a cone generated by vectors of the (finite) set X . Then for any vector $x \in C$ there exists a set $Y \subseteq X$ of linearly independent vectors such that x is a vector of the cone generated by the vectors of Y .*

Lemma 28. *The set $\mathcal{H} = \{a \cdot \mathbf{i} + F \cdot v \mid a \in \mathbb{Q}^+ \wedge v \in \mathbb{Q}^T\} \cap (\mathbb{Q}^+)^P$ is a convex polyhedral cone.*

Proof. The set $\{a \cdot \mathbf{i} + F \cdot v \mid a \in \mathbb{Q}^+ \wedge v \in \mathbb{Q}^T\}$ is clearly a convex cone and it is generated by \mathbf{i} and the column vectors of F and $-F$ so it is polyhedral. The intersection of this cone with the cone $(\mathbb{Q}^+)^P$ is polyhedral too. \square
