Document status and date:

Published: 01/01/2012

Document Version:

Publisher's PDF, also known as Version of Record (includes final page, issue and volume numbers)

Please check the document version of this publication:

- A submitted manuscript is the version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.
- The final author version and the galley proof are versions of the publication after peer review.
- The final published version features the final layout of the paper including the volume, issue and page numbers.

Recently, new approaches were taken towards the use of green solvents. Some examples are the substitution of organic solvents for supercritical fluids, “bio-solvents” or low-vapor-pressure liquids.

Among these possibilities, ionic liquids (ILs) attracted particular attention over the past years. One of their main advantages is that they can be designed by choosing the cation-anion combination to pursue the best performance as solvents for a certain purpose^[1]. The so-called “Task Specific Ionic Liquids”^[2] provide more suitable physicochemical properties or high degree of control of the solubility of gases in the solvent media. Together with their extremely low volatility, the judicious selection of the constituents contributes to their “green” performance. However, their “green” character is sometimes questioned. The high viscosity, production and purification cost make ILs technology in most of the cases not competitive compared with traditional solvents.

More recently, deep eutectic solvents formed by combination of a quaternary salt and a hydrogen-bond donor showed IL analogue solvent characteristics, with promising advantages. Some of them are low cost preparation, no need of purification, no water incompatibility, tunable phase behavior and solubility, low toxicity and biodegradability^[3]. A new family of low transition temperature mixtures (LTTMs) formed by natural molecules keeping the functionalities of some task specific and natural ionic liquids^[4] is explored in this work, evaluating their suitability as solvents for CO₂ capture.
