***Please check the document version of this publication:***

- A submitted manuscript is the version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.
- The final author version and the galley proof are versions of the publication after peer review.
- The final published version features the final layout of the paper including the volume, issue and page numbers.

# Towards viable nuclear fusion reactors

The combined effects of heat and neutrons on the microstructure of tungsten

A. Mannheim, J. A. W. van Dommelen, M. G. D. Geers

**Research goal** Can the heat extractor (divertor) of a fusion reactor withstand the extreme loads for a sufficient amount of time?

Figure 1: The top of the divertor (www.iter.org, left) consists of many tungsten monoblocks (right).

- Help to realize nuclear fusion
  - Increase lifetime divertor
  - Increase lifetime divertor monoblocks
  - Study mechanical evolution of the monoblock under the extreme loads
  - Study the microstructural evolution
- Research goal
- Study the combined effects of **heat** and **neutrons** on the microstructural evolution of tungsten

## Method 1 Grain level: neutron damage

Neutrons constantly produce displacement damage, in the form of vacancies (V), self-interstitial atoms (I) and dislocations, which interact and form clusters.

Using **cluster dynamics**, the concentrations as a result of the coupled evolution of the defects is computed.

Scale : Å – μm

Based on Li (2012), Stoller (1990), Yi (2015), Jourdan (2015)

## Coupling level 1&2

## 2 Polycrystal level: damage recovery

The neutron-induced defects are a form of stored energy in the material. This stored energy forms a driving force for grain growth and recrystallization.

A computationally efficient **mean-field model** is used. This model only requires two properties for the grains: their radius and their defect energy.

Scale : 1 – 100 μm

Based on Bernard (2011), Lopez (2015)

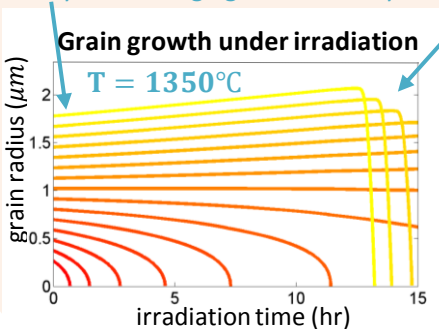

## Conclusion

- A multi-physics multi-scale model for the microstructural evolution of tungsten under heat and neutron irradiation was developed.
- The model can be used to make recommendations for extending the lifetime of the divertor by determining the optimal temperature window.

## Results

The smallest grains vanish because they have a large grain boundary

The larger grains vanish because a higher defect density has built up in them

### Competing mechanisms

- Grain boundary mobility
- Defect production
- Defect recovery
- Probability for formation of a new nucleus
