Publisher's PDF, also known as Version of Record (includes final page, issue and volume numbers)

Please check the document version of this publication:

• A submitted manuscript is the author's version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.
• The final author version and the galley proof are versions of the publication after peer review.
• The final published version features the final layout of the paper including the volume, issue and page numbers.

Introduction

During major surgery patients can lose large amounts of blood. To correct for this fluid loss, intravenous fluids are administered. Currently the goal is to restore normal hemodynamic values. A serious side effect of this treatment is fluid overload and edema formation\(^1\).

Whereas young patients can easily handle this fluid overload, elderly patients are at risk of developing hypoxia and organ failure\(^4\). This is an increasingly important problem, due to increased life expectancy.

Aim

Create a tool to provide more insight in the fluid balance of patients experiencing severe blood loss compensated by fluid administration, eventually to be used in clinical decision making.

Methods

The novelty of this project will be to combine a fluid distribution model with models of the cardiovascular and respiratory system.

A suitable fluid distribution model was found in literature, published by Gyenge et al (1999)\(^5\). The proposed model setup is shown in figure 3.

Preliminary results

Preliminary results are comparable to experimental data by Watenpaugh et al.\(^6\)

With the model we can provide extra information about the other compartments. In the figure below the effect of an infusion of 2.1 L saline in 30 minutes is shown.

Conclusion

The model by Gyenge et al. is capable of simulating the complex fluid distribution. To investigate the effect of fluid therapies and hemorrhage this model must be extended with cardiovascular and pulmonary compartments, especially considering regulation.
