Document Version:

Accepted manuscript including changes made at the peer-review stage

Please check the document version of this publication:

- A submitted manuscript is the version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.
- The final author version and the galley proof are versions of the publication after peer review.
- The final published version features the final layout of the paper including the volume, issue and page numbers.

PATHONE: from one thousand patients to one cell

Introduction

Digital Pathology is an image-based information environment, where tissue glasses are digitized by high-speed scanners. Whole-slide-images (WSIs) are generated and pathologists are empowered to analyze and diagnose them directly on a computer monitor.

In coming years, the technology uptake will harmonize the flow of images, information from Electronic Health Records (EHRs) and image analysis results. However, integration of this heterogeneous data into a single application is still one of the challenges in the evolution of pathology to a digital practice.

Aim

- Provide a tool to facilitate simple queries in an EHRs database
- Directly link patients' data to Whole-Slide-Images
- Introduce WSIs-filtering by slides content and image analysis results
- Empower researchers tasks in one-single-screen solution

TASKS

Standard researchers' tasks enabled by PATHONE, currently achieved by accessing separate services.

Task 1. Search a cohort that fits the research question in the clinical information system.

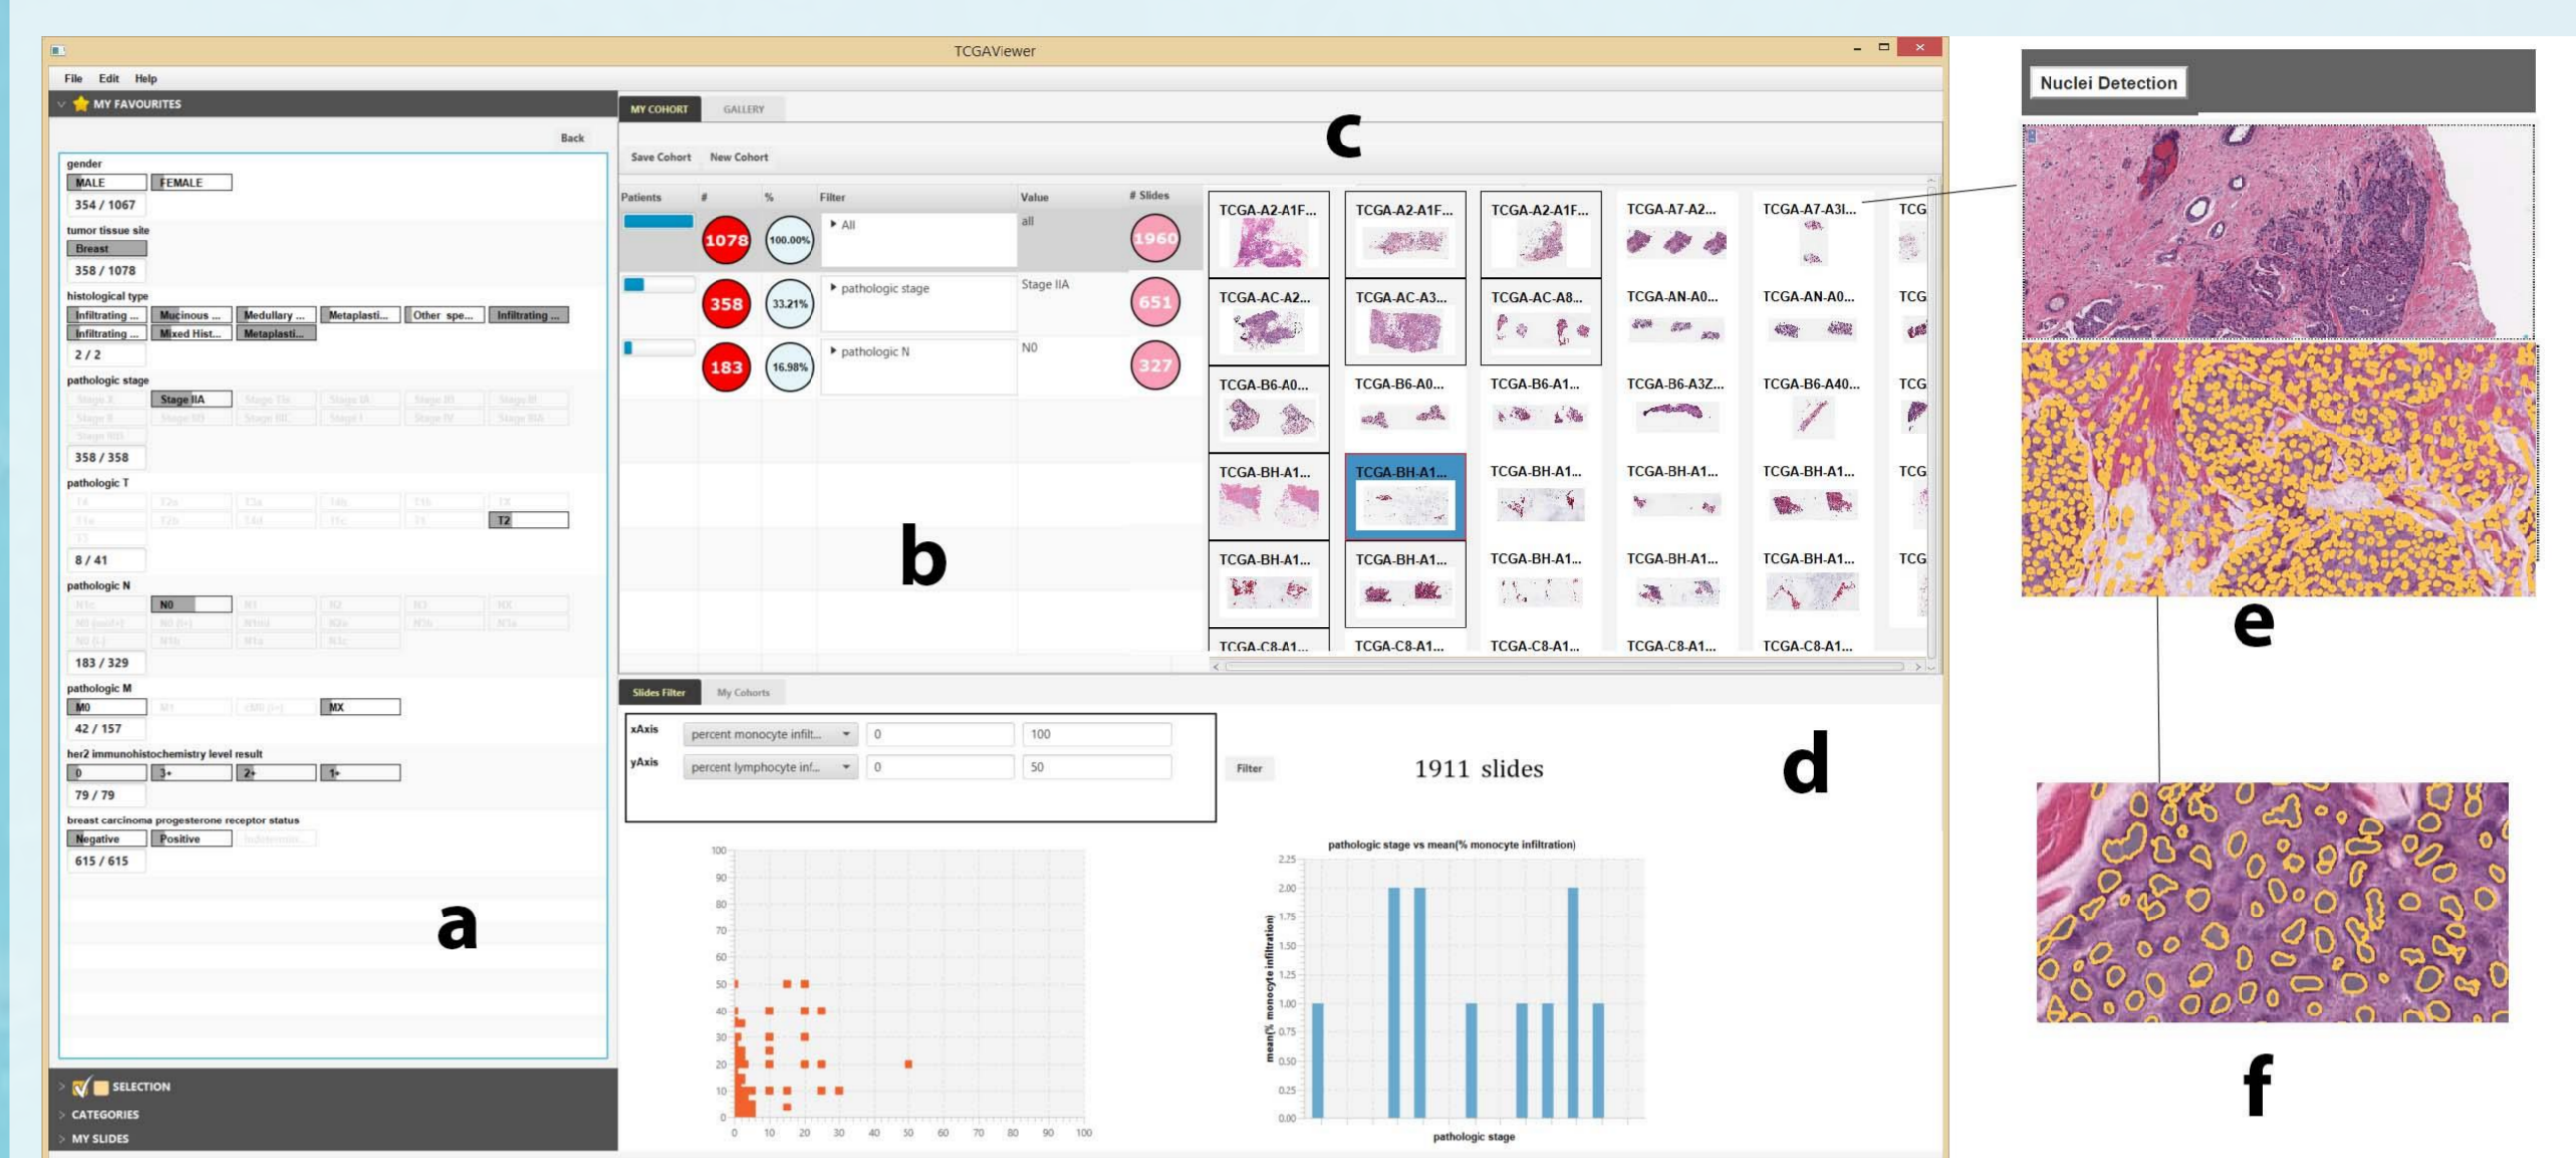

Task 2. Look for respective tissue slides in the archive

Task 3. Make a list of suitable images for image analysis or clinical studies.

Task 4. Pre-process images and run detection algorithms on digital slides

Application

- Cohort Selection (**Task 1**): Patients can be filtered by a click on each box, representing a different value for each attribute. Current number of patients still available is represented as a gray bar
- Current query information: Insight on current cohort selection
- Slides Gallery (**Task 2**): respective patients' images are immediately displayed
- Slides filtering (**Task 3**): Images can be filtered by biological information
- Example of nuclei detection (**Task 4**): User can run an algorithm on the same screen on a desired slide.
- Analysis of results: User can inspect the computed features on by a standard virtual microscopy viewer.

Future work

We implemented a visualization tool to enable researchers to perform the standard steps which they are used to go through before starting image analysis studies.

We collected informal feedback to assess the satisfaction of potential users.

We aim to extend the tool with machine learning techniques to enhance the explorative experience and to integrate more image analysis computations to enhance the slide filtering on more biological information.
